THE GAS COMPANIES AND ELECTRIC LIGHTING.

When discussing, as we have often had to do of late, the attitude towards electric lighting assumed by those Local Authorities who own gas works, we have always maintained that it is a matter of indifference to electrical trades whether the business of supplying electricity is carried on independently by them or is amalgamated with existing municipal gas undertakings. And this we still believe to be the case, always provided the amalgamation is effected with the honest intention of supplying and not extinguishing the new illuminant. The same arguments, with the same reservation, apply equally to private Gas Companies in general. If they took up the business of electric lighting with no other motive than to act fairly by it and by the public, there is reason to believe that electrical engineers would not suffer by the devolution, but rather that they would be the gainers. They are, therefore, able to discuss in an impartial spirit the further questions whether it would be to the advantage of the Gas Companies themselves to enter upon the business of electric lighting, and whether the public would in that case be as well served as they expect to be by the undertakings which are about to devote themselves exclusively to that line of business.

The latter of these propositions admits of an affirmative answer being given with little or no hesitation; for all the conditions seem to favour the old-established purveyors of light continuing to serve the public as they have done for generations past, even though the article supplied has undergone a material change. The Gas Companies, it is true, have never possessed a monopoly of every form of lighting; candles and oil are still outside the sphere of their operations; and into whatever hands electric lighting may fall, some applications of it would remain with private undertakers, just as in some instances does the manufacture of gas. But for public and domestic purposes lighting by means of gas and by means of electricity are operations sufficiently alike to

Digitized by Google

warrant their being conducted by one and the same contractor, and even to recommend it on economic and administrative grounds. The companies have a large command of capital, they possess the necessary organisation, they would have the same demands to satisfy, and they have had experience in satisfying them which none but themselves can pretend to. Not only this, they are already in almost complete possession of the field, and could supplement their existing plant and appliances with the requirements for the new illuminant at less cost and perhaps with greater efficiency than could any rival undertaker. The argument on public grounds therefore seems to be unanswerable, and we have by no means exhausted it.

Something, no doubt, can be said on the other side, chiefly based on the prejudice which undeniably prevails against existing monopolies. But, without discussing the justice or injustice of that prejudice, it may be confidently asserted that the public have no interest in, and would not benefit by the extinction of such monopolies to their financial ruin. So far, therefore, from the prospective successful rivalry of the electric light being an argument for its elevation to a position of independent monopoly, it is rather a reason for desiring its absorption by the ancient and still thriving monopolists. If there is to be, sooner or later, a desperate competition between the two systems of lighting, it will be to the detriment of both; and it is hardly doubtful which of the two would suffer most. Almost certainly the electric light will be hampered in its progress, if not permanently enfeebled, by competition directly that period of conflict is reached; and from this point of view also, if they want the electric light, the public would not be averse to its being supplied by the existing Gas Light Companies.

The other proposition touching the interests of the Gas Companies themselves is not so easily answered. But it is one that they will have to consider and answer before many years are over. At present we see hardly any disposition among the directors or shareholders to give the question the attention it deserves; and we know of only one gas undertaking in England—and this a municipal body—that has taken up the business of electric lighting, although numerous instances of the kind are occurring in America. Nevertheless, the subject is being seriously discussed in, at least, one influential organ of gas industry in this country; and at the recent annual meeting of the members of the Gas Institute a Paper was submitted and printed, though not publicly discussed, putting the question categorically, "Shall Gas Undertakings supply Electricity?" and answering it with an emphatic Yes. The writer affirms, though we cannot corroborate his figures, that there are already in America quite 100 Gas Companies supplying electricity in connection with one system —the Thomson-Houston—alone; and surveying the progress which electric lighting is making here, and may be reasonably expected to make, in the hands of its present promoters, he presents the issue in the following pertinent query: "If things continue like this, where will the Gas Companies be in a few years time? They will have in every district where there are gas works, an Electric Light Company competing with them, and then they will see that it would have been well if they had obtained a footing themselves." What follows is more problematical. "Assuming," says the author, "that Gas Companies supply electricity, and looking into the far future, who knows but that gas works will become electric light works, and that, as the electric light enters into universal use, so will gas die out?" If gas undertakers could be persuaded of this, they would assuredly lose no time in acquiring Provisional Orders for supplying electricity. What deters them at present is their confidence in the supremacy of gas, and their scepticism as to the future of electric lighting. To a similar question propounded at a recent meeting of the American Western Gas Association, the president answered, "In some situations, yes; in others, no." Probably he meant Yes where there is a vigorous demand for it, and No where there is not. English Gas Companies are perhaps waiting for the demand which will satisfy their ideas of vigour. When that time arrives, however, the supply will not be so easy of acquirement. But we do not share the apprehensions of some of our readers that the Gas Companies would not supply the electric light with sufficient liberality. That must depend entirely on the reality and extent of the demand; and to assert that the Gas Companies would not respond to it, is equivalent to a confession that the demand may not be great enough to make the business remunerative—a conclusion as discouraging to Electric Light Companies as it would be welcome to Gas Companies. In short, if the former succeed in their venture the latter could hardly fail to succeed likewise; and, without in the least desiring it, much less recommending it, we have not the least doubt that the gas undertakers will become electric lighting undertakers directly they find it is to their interest to adopt that course.

OBITUARY.

M. AUGUSTE FREY.

We regret to announce the death of M. Frey, the Director of the International Telegraph Bureau at Berne.

M. Frey became Director-General of Swiss Telegraphs in April, 1873, and in that capacity attended the Telegraph Conferences of St. Petersburg, London, and Berlin. Last March he was appointed Director of the International Bureau, in succession to the late M. Curchod; and although suffering from a painful internal malady the doctors thought he had at least two years' work before him. However, when the Paris Conference opened in May he was unable, through illness, to be present, and his absence was feelingly alluded to by Mr. Lamb in the last sitting of the Conference, on 21st ult.

M. Frey was a man of genial habits, and made himself generally liked and appreciated by all who knew him.

MR. JOHN BOURDEAUX.

We regret to record the death, after a long illness, on Wednesday last, at the age of 55, of John Bourdeaux, who was the Chief Engineer of the Submarine Telegraph Company up to the time of the acquisition of its cables by the Post Office.

Mr. Bourdeaux was one of the few remaining representatives of the earlier telegraphists, having entered the service at the age of 14. In his time he probably repaired more shallow-water cables than any other cable man.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

§ 1. **Transformer Systems.**—The employment of the alternate-current transformer for electric-current distribution has changed in many respects the practical possibilities of the supply of electric energy for lighting purposes in large towns and in districts in which great distances, comparatively speaking, separate the centres of consumption and supply. By its aid it has become possible to deal with problems in electric distribution which are less amenable, or perhaps, commercially speaking,

* This series of articles is a continuation of those which appeared in *The Electrician* under the title of "The Alternate Current Transformer," by the same Author, and which have since been largely extended and republished in book form. All rights are reserved.

Digitized by Google

unprofitable, when attacked by other methods; * and its enormous extension in six or seven years in Europe and in America is in itself evidence of the utility of the method. In examining the results as a whole that have been obtained by the employment and adaptation of the transformer for this purpose, we shall proceed to describe the principal systems at work, and the details of the installations of transformer systems in typical places in which it has established itself as a fit solution of the practical difficulties which there presented themselves to be overcome. The systems now occupying positions of importance, and on the lines of which, in different places, electric distributions of varying degrees of magnitude are being carried out, are chiefly those connected with the names of Ganz and Co., of Budapest, operating the methods of Messrs. Zipernowsky, Déri, and Bláthy; the Westinghouse Electric Lighting Company, and the Thomson-Houston Electric Lighting Company, in the United States, operating the systems elaborated by the well-known inventors connected with them. In England, the now familiar systems of the London Electric Supply Corporation (Mr. S. Z. de Ferranti), the Brush Electrical Engineering Corporation (Mr. Mordey), and the House-to-House Electric Lighting Company (Messrs. Lowrie, Hall, and Parker). The Metropolitan Electric Supply Company of London, employing for the most part methods and machines of the Westinghouse Electric Light Company, as well as Elwell-Parker

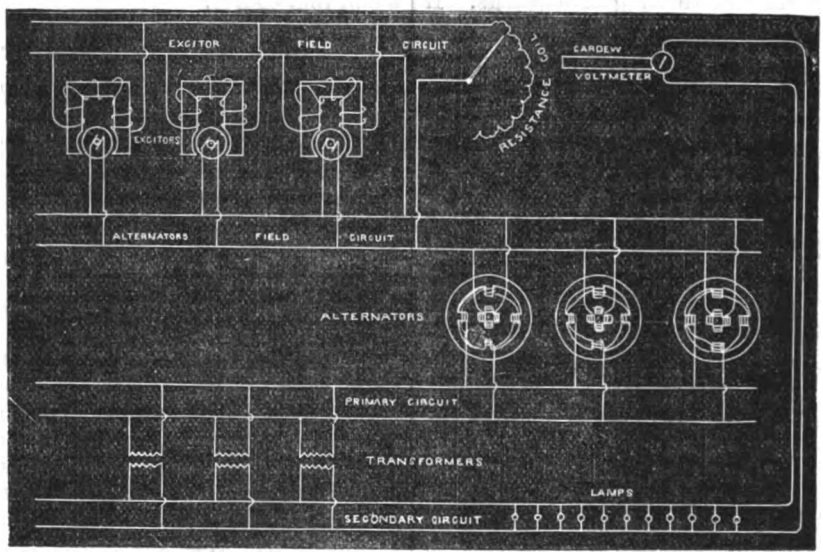

FIG. 1.—Arrangement of Alternators, Exciters, and Transformers in Ganz system of Electrical Distribution.

dynamos and transformers, may be considered as a connecting link between English and American ideas. This list by no means exhausts the names of designers or manufacturers of transformers, or of its necessary adjunct, the alternating dynamo. Apart from efforts of pioneers we have excellent designs for these separate elements connected also with the names of Messrs. Siemens, Gramme, Hopkinson, Goolden, Kapp, Wilde, Snell, Swinburne, Sharpe and Kent, Elwell-Parker, R. Kennedy, and many others; but the above-named six or seven complete systems comprise for the most part the best known apparatus in wide use for the distribution of electric energy by transformers; and some account of the machines, appliances, and methods in use by each respectively, taking typical examples, will now be given. The order in which they will be mentioned has, however, no reference to their historical order of development, nor to their relative importance.

§ 2. **System of Ganz (Zipernowsky, Déri and Bláthy).**—The methods of transformer distribution, which have been elaborated and put into execution by the inventive ability of Messrs. C. Zipernowsky, M. Déri and O. T. Bláthy, of Budapest, have enabled the great firm of Ganz and Co. to establish a special electric lighting department and to undertake on a large scale the production of all the appliances and details which have been worked out into the complete system which bears their name. Nearly seventy central stations of different degrees of magnitude have been set in operation by them up to the present time (1890), in which electric energy is distributed to arc and incandescent lamps from central stations, about 1,000 arcs and 100,000 incandescents being in all supplied. The elements of this system comprise (i.), An alternating-current dynamo machine; (ii.), An exciting continuous-current dynamo; (iii.), The alternating transformers; and (iv.), Special regulating devices, which have for their object the maintenance of a constant pressure, irrespective of consumption, at some point or points in the distributing system. The system may be described as a *parallel* system in its entirety, that is to say, the exciting dynamos are arranged in parallel between two exciting mains, the field-magnets of the alternating-dynamos being in parallel between the same mains (*see* Fig. 1). The armatures of the alternators are arranged in parallel between a pair of primary mains, working, if need be, in step with each other, and the primary coils of the transformers are all arranged in parallel between the same primary mains. The secondary circuits of the transformers are arranged in parallel with the lamps between the same secondary mains. The exciting dynamos are shunt dynamos, and the field-magnets circuits of these dynamos are also all arranged in parallel, and take currents off the main circuit of the exciting dynamos, into which the armatures of the exciters are as well all joined in parallel. There is a variable resistance interposed in the circuit of all the fields of these exciters, by the variation of which the strength of the exciter field can be varied, and hence the electromotive force of the exciters. The field-magnet circuits of the alternators being all joined in parallel with each other, and with the armatures of the exciters, it is obvious that the variation of this intercalated resistance can be made to change the strength of field of the alternators; and hence the electromotive force of these machines within certain limits. The transformer circuits are joined in parallel between the primary and secondary mains. From some points in the secondary distribution system, which may be called the electrical centre of the network, a pair of voltmeter wires can be brought back to the station; and by an arrangement presently to be described, the regulating resistance can be properly varied so as to keep the electric pressure at this electrical centre of distribution constant. Voltmeter wires, or *feeling wires*, may be brought back to the station from more than one point, and the pressure at any one of these points regulated as the demand for current requires. The variation of one resistance controlling the field of the excitors, therefore, is able to effect the regulation of the electric pressure in the secondary circuits over large areas of distribution.

(To be continued.)

* The arguments *pro* and *con* in the case of alternate transformers and secondary batteries for central station electric lighting need not be entered into here; but we refer the reader to Mr. R. E. Crompton's excellent Paper, and the discussion thereon in the *Journal of the Institution of Electrical Engineers*, Vol. XVII., 1888.

THE POST-OFFICE JUBILEE CONVERSAZIONE.

A brilliant gathering at the South Kensington Museum, which rarely before held so many visitors, celebrated the jubilee of the Penny Post on Wednesday last.

The work of the Post-Office, sorting, stamping, and making up mails, was busily carried on among the classical statues; and in one of the longest galleries was displayed a collection of historical and modern telegraphic apparatus.

Amongst the recently developed instruments were specimens of the double sounder, which consists of two plate sounders, tuned to different notes, as in the Bright's bell. The peculiarity of the instrument is the hood which covers the sounders and the relay. Its shape is suggestive of a hall porter's chair. The sides are made of wood, and the curved back is composed of a sheet of perforated zinc, covered on each side with thin mahogany veneer. This has been found to give a remarkably sonorous resonance; the shape is the outcome of experiments with the view of focussing the sounds on to the ears of the operator. Several of these instruments can be used side by side, without any confusion of sound. A specimen of the instruments used with the latest development of Delaney's multiplex system are shown. The contact ring is provided with 144 working segments, besides correcting segments. When the instrument is worked with six circuits, each one receives a current from 24 contacts in one revolution of the rotating arm. Each operator therefore receives a current 72 times in a second, a speed which, if he is not aware that he was on a multiplex line, would convince him that his circuit was being worked with a continuous current, and at the same time, would convince five others, whose messages have to pass during the pauses of which he is unconscious. The La Cour phonic wheel, which is used to synchronise the transmitter and the receiver, is worked with a vibrating reed, making 90 vibrations per second. There are 30 armatures on the wheel, and it is, therefore, driven at three revolutions per second. Although a current of 0·2 ampere is sent through the contact maker on the reed, all sparking is prevented by the use of a condenser shunted round the magnet. In dealing with these pulsatory currents, the relay used is of considerably larger dimensions than the ordinary pattern. A large self-induction is produced by an increased number of turns of wire, and by the use of a large iron core. A condenser, coupled as a shunt to the coil, discharges during the time of disconnection; and the current so discharged, coming between the two portions of the main current, fills up the gap to a great extent, and tends to convert a discontinuous current into a pulsating current. Each instrument will work with as little as half a milliampere, but six milliamperes are used in practice. The pulsatory current requires the use of higher volts; but the current on the line is actually less than with a Wheatstone, which needs fewer cells, but 25 to 30 milliamperes. The Post-Office line men say that a live multiplex line is considerably more comfortable to handle than a Wheatstone. Among the rows of complicated glittering instruments which seemed almost out of place among the brilliant dresses of the thousands who thronged the corridors, was a length of a few feet of a telegraph post, having a large hole, which had been excavated by a woodpecker. A stuffed bird of this kind—a remarkably fine specimen—was mounted as if at work on the post, under the impression that the noise of the wind among the wires was due to the "murmuring of innumerable bees," or whatever insects form the food of the pretty creature. A bird mounted in a similar way was shown at the Paris Exhibition of 1881; but this is a real English specimen, shot only a few months ago.

The historical display included a collection of insulators, showing the gradual development of their design. Beginning with a mere porcelain ring, the surface was increased, and the insulator took the form of two solid cones, base to base. Then it assumed an hour-glass shape, or two hollow cones, point to point, the wire in both cases running through the axis. Then a suspending hook-shaped insulator was tried, first of porcelain, and then of glass, and was provided with a zinc cap. This was intended to act in the same way as the zinc cap which is used on the end of an astronomical telescope, viz., to concentrate upon itself the formation of dew. It unfortunately extended its accommodation to spiders. It was, as might be guessed, the invention of Mr. Latimer Clark. The next pattern, in which the cap was made of glass, was too fragile. The cap insulator was then introduced by Varley, and a few modifications and an increase in size resulted in the ordinary Post-Office pattern of insulator.

The great attraction of the evening was undoubtedly the electrophonoscope, which was exhibited to illustrate what telegraphy is likely to be in 1990. It is the joint invention of two gentlemen who are the highest authorities on the construction of delicate mechanism of telegraphic instruments, and who have had the collaboration of the Post Office officials. Some four or five different suggestions have been made from time to time of methods whereby it might be possible to enable a distant object to be seen by the aid of electricity. All these have depended upon the use of selenium, a most disappointing material for the purpose. These schemes all depended upon an optical illusion produced by points illuminated in rapid succession, or by quickly-moving mirrors. While the present system has something in common with the latter method, the illusion is of a very different nature. The system is not patented, and we can say nothing more about it but that the mechanical details of construction which we were allowed to examine were admirably adapted for the purpose; and the result was, of its kind, nearly perfect. The sender of the message, speaking through a telephone, sees with very fair distinctness the person at the distant end, and *vice versa*, the face of each being brightly illuminated by electric light.

THE MAGNETIC CIRCUIT.

BY E. T. CARTER.

The principle of the magnetic circuit having now become so generally recognised, and so universally adopted in practical work, it will be instructive to compare some of the points of analogy between it and the electric circuit. The "Ohm's law" of the magnetic circuit is an accomplished fact; and the employment of it has greatly facilitated electro magnetic calculations. We have laws of magnetic "conductors" in series and in parallel; of opposing or helping magneto-motive forces distributed round the circuit, either in branched or main parts of that circuit; we might even with safety, and possibly with advantage, use the terms "impedance," "back M.M.F.," "resistance equivalent," and many other terms that are employed in the discussion of electric circuits; for the ideas expressed by them are common to magnetic and electric circuits. It is my intention, in this Paper, to carry the points of this analogy a little farther than is usually recognised among practical engineers, hoping that the result may prove of some value to all who deal in matters magnetic.

The theoretical conceptions of magnetic and electric potentials at any point in a field of force are identical. In each the potential is measured by the line integral of the force exerted when unit quantity is moved from the boundary of the field to the point in question. The potential difference, therefore, between any two points is the work done in moving a unit charge (if the field is electrical), or a unit pole (if the field is magnetic), from one point to the other. Imagine a unit charge (electro-magnetic) inserted into an electric circuit at any point, it will tend to move along with the current; that is, its potential will tend to fall. But if we push this unit charge up the circuit against the current we raise its potential, and do an amount of work which is a measure of this rise. The work done may be expressed either as the line integral of the force acting on the charge, or as a function of the electrical resistance of the path taken by the charge and the current opposing it. In mathematical language—

$$\text{P. D.} = \text{W} = \int_0^l \text{F} \,.\, dl = \int_0^R \text{C} \,.\, d\text{R}.$$

The former of these integrations depends upon our conceptions of force and energy; the latter upon our notions of the re-

Digitized by Google

lation between current, resistance and potential difference. It must be further explained, however, that the latter expression is accurate only when there are no E.M.F.'s actually in the path of the carried charge. When such E.M.F.'s exist—

$$\text{P. D.} = -\Sigma e + \int_o^R C \,.\, dR,$$

where Σe is the algebraic sum of these E.M.F.'s. This can be transformed into

$$\text{P. D.} = -\Sigma e + \int_o^R C \,.\, d\,\frac{l}{k\,A} = -\Sigma e + \int_o^l \Delta \,.\, d\,\frac{l}{k},$$

where

Δ = current density,
A = sectional area,
k = specific electrical conductivity,
l = length of conductor whose potential difference is P. D.

Now, if the charge is carried completely round the circuit its P. D. is not finally altered.

$$\therefore \Sigma e = \int_o^l \frac{l}{k}\,\Delta \,.\, d\,\frac{l}{k} = \int_o^l F \,.\, d\,l,$$

which shows that the effective E.M.F. in any circuit-carrying currents may be measured by the line integral of the force exerted on a unit charge moved once round the circuit against the current, any path in the conductor being taken; or that it may be measured in terms of current density, specific conductivity, and length of circuit. In practice the latter method is the one employed, with slight modification.

Considering, now, the magnetic circuit: if a unit pole is placed in the circuit anywhere, and carried along against the lines of induction, its potential is raised, and the work done is a measure of this rise. When there are no magnetomotive forces actually in the path of the pole,

$$\text{P. D.} = \int_o^l F \,.\, dl = \int_o^R N \,.\, d\,R,$$

The latter of these expressions arising from our conceptions of magnetic flux N_1, magnetic resistance R, and potential difference P. D.

But when M.M.F.'s occur in this path,

$$\text{P. D.} = -\Sigma m + \int_o^R N \,.\, d\,R,$$

where Σm = sum of M.M.F.'s.

$$\therefore \text{P. D.} = -\Sigma m + \int_o^R N \,.\, d\,\frac{l}{\mu\,A} = -\Sigma m + \int_o^l \mu\, B\, d\,\frac{l}{\mu}.$$

And if the pole is carried once round the circuit, since P. D. = 0, the effective M.M.F. can be measured either as the line integral of the magnetic force once round the circuit; or as a function of the intensity of magnetic induction, the permeability, and the length of the magnetic circuit.

The symmetry between the expression for the two circuits is remarkable and suggestive:—

$$\int_o^l \frac{l}{k}\,\Delta \,.\, d\,\frac{l}{k};\ \text{(electric circuit).}$$

$$\int_o^l \frac{l}{\mu}\,B \,.\, d\,\frac{l}{\mu};\ \text{(magnetic circuit).}$$

Many things of practical importance are suggested by this very close analogy. In the first place we can obtain from these integrals two very symmetrical expressions for force in the circuit; viz.:

and,

$$F = \frac{\Delta}{k};\ \text{in the electric circuit,}$$

$$F = \frac{B}{\mu};\ \text{in the magnetic circuit.}$$

This indicates the fallacy of confounding "lines of induction" with force; and of calling the former "lines of force," except when they pass through a portion of the circuit of unit permeability. There is a growing tendency to speak of "lines of force in the iron" when magnetic induction is intended.

In the second place, there is a very strong suggestion of the practical possibility of a set of magnetic units resembling those for the electric circuit. In matters electrical, when we had learned about the "line integral of the electric force," we straightway forsook it for the more practical ohm and volt and ampere. This could, and probably should, be done in the case of the magnetic circuit. A practical set of units, with convenient names, would be a great boon. The two complex functions, hysteresis and saturation, render this more difficult for magnetic "conductors"; but with a set of simple constants this difficulty can in great measure be overcome. As calculations are usually conducted at the present time, much unnecessary complication arises from the use of so many constants; these chiefly being caused by the use of a mixture of C.-G.-S. French and English measures. In Tables I. and II. these constants are reduced to a single constant for English measure; as this has been found greatly to shorten calculations for magnetic circuits.

K_1 = number of ampere-turns per foot length of magnetic conductor.
K_2 = magnetic resistance (C.-G.-S.) of one foot length and one square inch section.

Thus, to determine the number of ampere-turns required on account of a portion of the circuit L feet in length, the formula is simply

$$\text{ampere-turns} = K_1 \,.\, L,$$

and to determine the magnetic resistance of any portion

$$R = K_2 \,.\, \frac{L}{A},$$

where A is the sectional area in square inches; L being in feet as before.

For air, the constants, on the same system, are

$$K_1 = 3{\cdot}760\ B;$$
$$K_2 = 4{\cdot}7245.$$

STENO-TELEGRAPHY.*

Under the name of steno-telegraphy, M. G. A. Cassagnes designates a new telegraphic system founded on the combination of mechanical stenography with telegraphy. This system can be applied indifferently to any stenographic machine worked by a key-board; but, as the inventor had specially in view Michela's stenographic machine, which he successfully adapted to the apparatus which has been experimented with on the French telegraphic lines, it is to this special application that the present notice refers.

Michela's stenographic machine is exceedingly simple in construction and extremely ingenious in principle. By means of 20 signs and their combinations, Michela's machine can represent all possible phonetic sounds constituting any language. As soon as spoken, the words are, so to say, decomposed by the ear of the operator at the key-board; the graphic representation of syllables is printed in small distinct lines on a tape of paper, and there only remains afterwards to read these lines from left to right to reproduce the language spoken, whatever it be. With Michela's machine, a skilled operator can stenograph 200 words per minute in a language with which he is familiar. This is more than is wanted to follow the fastest speeches; the number of words pronounced by the best known orators of the various countries vary from 80 to 180 per minute, giving an average of 130.

The aim that M. Cassagnes had in view was to reproduce at a distant station the stenographic tape that Michela's machine produces *in loco*, and at the same speed. To obtain steno-telegraphy, it is sufficient to place at each of the two distant stations one of the two principal constituents of the stenographic machine; the keys and the printing styles. The keys are placed at the transmitting station, and the styles at the receiving station. If a single-line wire is used it is necessary that the key-board should only be employed as a multiple contact key, and special apparatus be used to receive and distribute the electric currents. To transmit currents coming from several contacts to corresponding receiving apparatus by means of a single-line wire, one of the most satisfactory solutions consists in the use of a system of synchronous distributing and receiving apparatus.

The diagrammatic arrangement of the steno-telegraphic system is as follows:—Figs. 1 and 2 represent respectively the transmitting and the receiving stations. The key-board of the manipulating apparatus, placed at the transmitting station (Fig. 1), consists of 20 keys, C C, provided with contact pieces alternately connected with the positive and negative poles of a battery, P P', the middle of which is put to earth. The keys are also connected with the contact segments of a distributing commutator D. A brush F, fixed on the spindle of a soft iron toothed wheel A, is kept in a state of continuous rotation. This brush, as it passes successively over each segment, makes the connection between this segment and the line L L. At the receiving station (Fig. 2) a similar distributing commutator D', having a brush F' rotating in perfect synchronism with that of the transmitting station, has its contact segments in connection with polarised relays R_3, R_4, R_5.....R_{20}. It is thus easily seen that the currents sent on the line by the depression of the keys of the board, are received, at the other station, in the coils of these polarised relays, that they will act on their armatures and close the circuits of a local battery P'_3. The current from this battery will work the styles of the printing apparatus corresponding to the keys depressed at the transmitting station. When the stenographic signs corresponding to the depressed keys have been printed on the tape of the receiving apparatus, the tape is moved forward so as to allow of the printing of a new line of signs, and so on. There is thus obtained, by means of a single-line wire, the exact reproduction of the tape as heretofore described. The printing apparatus I (Fig. 2) contains 20 styles on which are engraved the stenographic signs corresponding to the 20 keys of the board. Each of these styles can be pressed against the paper tape by the armature of a corresponding electromagnet; the coils of the 20-electromagnets e, e, e are connected at one end with the binding screw V and at the other with the abutting contact screws v_1, v_2, v_3, &c., of the relays.

The system having been thus described in its chief parts, let us now examine in detail the series of currents and of corresponding motions which follow the depression of any combination of keys on the board. A stenographic line is produced by the depression of a certain number of keys (12 at the maximum). Suppose, for instance, that the three keys 3, 4, and 6 are depressed. When the brush F arrives on contact 3, F' is on contact 3'; a current travels along the line and throws the armature of the relay R_3 on the abutting contact screw; the circuit of the battery P'_3 is closed,

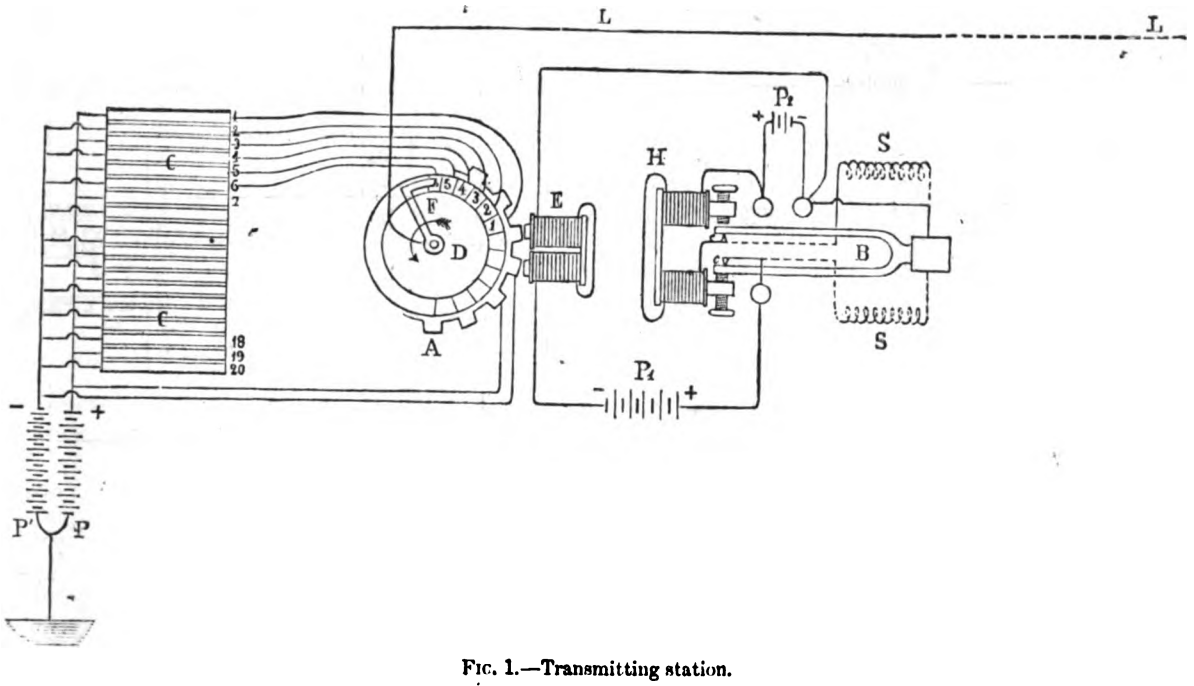

FIG. 1.—Transmitting station.

through the electromagnet e_3, and the style p_3 prints its sign on the paper tape stored at G and passing over the styles. The moment after, the brushes arrive on contacts 4 and 4', then on 6 and 6'. The battery P'_3 is successively closed through e_4, e_6, and the styles p_4, p_6 are thrown up against the paper tape which remains at rest during the printing of the stenographic line. The printing of the line is then finished; the combination of keys which have been depressed is reproduced on the paper.

The relays are brought back to their position of rest by local currents. When the last relay of the combination has been brought back, the circuit of battery P'_3 is open, and at this instant, the armature of an electro-magnet M, which is also in this circuit, is released, and the paper moves forward for another line. The system has now come back to the starting point, and a new combination of depressed keys, on a second turn of the brushes, will give rise to a second stenographic line. After each current the line is put to earth by the brushes themselves.

In order to obtain these results by means of a single wire, there can be employed any system capable of rotating the two brushes F and F' on the two commutators D and D' in perfect synchronism, and of correcting the variations which from one cause or another, arises in the speed of these brushes. The system made use of by M. Cassagnes is the synchronism by means of the phonic wheel of M. Paul La Cour, of Copenhagen. The system (Figs. 1 and 2) consists in an electro tuning-fork, B, the vibrations of which are kept up by the intermittent passage of the current of a constant battery, P_2, in the coils of the electro-magnet H. The interrup-

* From a pamphlet by M. L. H. Despeissis.

Digitized by Google

tions are produced by the very vibrations of the tuning-fork, which close and open a contact at the extremity of one of the prongs. The vibrations of the other prong are utilised to send interrupted currents from battery P_1, in the coils of the electro-magnet E, the soft iron cores of which are thus alternately magnetised and demagnetised. In order to prevent the extra current-sparks between the prongs of the tuning-fork and the contact points, two high resistance shunts, S S, are placed between them. Opposite the poles of electro-magnet, E, is placed a soft iron wheel, A, with teeth on its circumference, and on the spindle of which is mounted a box-wood reservoir full of mercury, acting as a fly-wheel. On the prolongation of the spindle is also fixed the brush F, which rubs on the contacts of the commutator D. If the wheel is first rotated by hand at a certain speed, it will continue in motion on account of the successive attractions which the teeth undergo at their passage near the poles of the electro-magnet E. The wheel will thus rotate at a speed determined by the frequency of the tuning-fork and the number of teeth on its circumference. This speed will be therefore practically constant.

The receiving station consists of a set of similar apparatus; and it is easily understood that, if both wheels have the same number of teeth and the frequencies of the tuning-forks have been adjusted to be nearly the same, the two speeds will be very approximately equal. In order to render them rigorously identical, M. La Cour makes use of the following device: The commutator of the transmitting station is provided with two special contact segments, one of which is connected to the positive, and the other to the negative pole of the line battery. At the corresponding position of the receiving commutator (Fig. 2) is placed a single contact in connection with the coils of a polarised relay *r*. The wheels once put in motion and their speeds not being exactly the same, after a certain time the brush F will pass one of the two correcting contact segments of the transmitting station when F′ passes on the correcting contact of the receiving station. At that moment, a positive or a negative current will pass in the relay *r* according as F is on one or the other of the transmitting correcting contacts. This current will throw the armature of the relay *r* on one side or the other, and will introduce or cut off an adjustable resistance from the circuit of the battery P'_2. There will, therefore, be more or less current flowing through the electro-magnet H′, and the tuning-fork B′ will vibrate a little quicker or a little more slowly, according to the case, so that it will always be maintained at a mean speed equal to that of B. The two wheels will therefore always rotate at the same number of revolutions, and, at every instant, the two brushes F and F′ will always be on corresponding contacts of the two commutators.

Such is, in principle, the action of the apparatus in its simplest form. But, to make it practically serviceable, M. Cassagnes has been led to numerous modifications, either in the details of the commutators of the phonic wheels, so as to adapt them to the special object he had in view, or in the electrical connections so as to increase the output. We cannot enter into the detail of all these items, and can only point out some of the most important. Instead of having 20 contact segments distributed round the whole circumference of the commutators, they can be supposed grouped in sectors, the same commutator carrying two or three sectors of 20 contacts each, for instance. In this way, the formation and the transmission of a stenographic line can be repeated twice or three times in a turn, either by means of a single keyboard, the keys of which are connected to two or three different contacts, or by having independent key-boards connected each to the contact of a separate sector. Another simplification has arisen from the fact that certain keys are never combined together, and therefore certain pairs of keys can be connected to one and the same contact segment on the commutator. As these are always neighbouring keys that do not combine one with the other, one of them is made to transmit positive and the other negative currents; and, at the receiving station, the corresponding contact is connected with two relays oppositely polarised. The number of contacts can thus be reduced to 12 for each sector, and, the brushes rotating at the same angular speed and the number of sectors being the same, this allows of a greater duration in sending the currents.

The following are some of the experiments to which the steno-telegraphic apparatus has been submitted. In the first series of experiments the transmitting and receiving apparatus were placed alongside, in the same room of the Ministry of Telegraphs, 103, Rue de Grenelle, Saint-Germain. The two earths were different, and the up and down wires were on different posts.

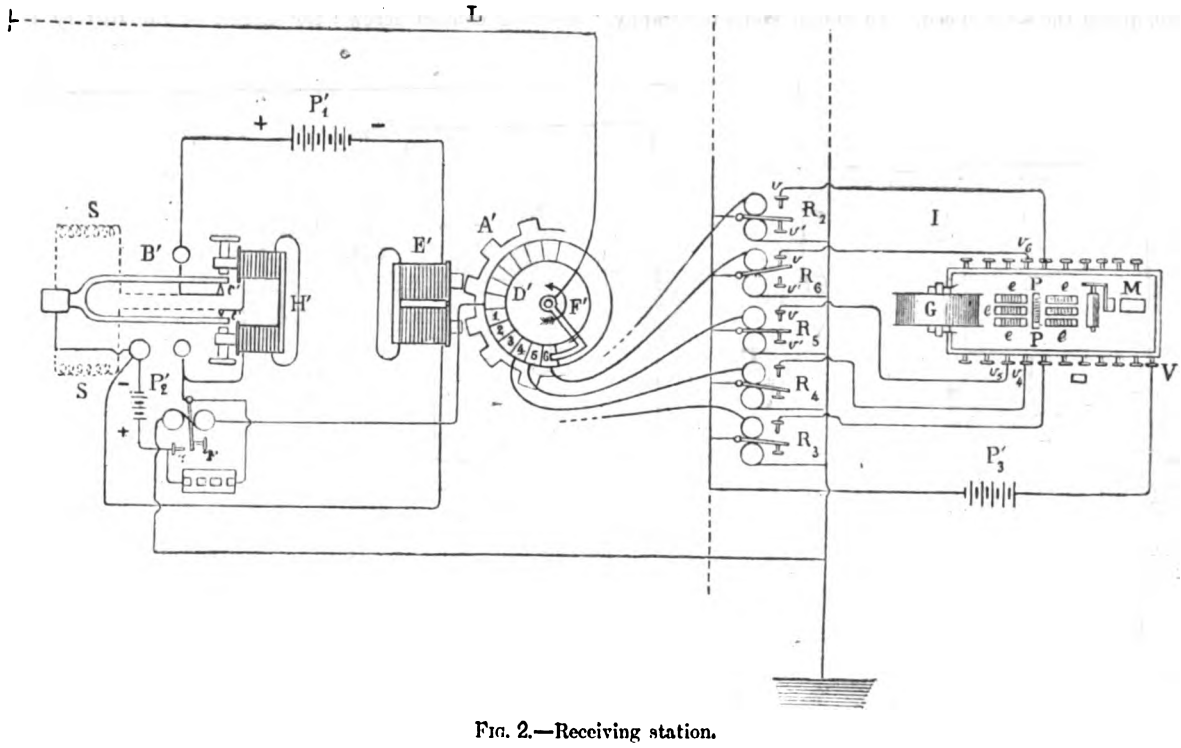

FIG. 2.—Receiving station.

Experiment, October 29th: Paris, Orleans and back. Circuit of 245 kilometres, out of which 19 kilometres underground. Resistance of circuit 2,000 ohms. Battery, 60 Callaud. Experiment, October 31st: Paris, Tours and back. Circuit of 480 kilometres, 35 underground. Earth at Asnières. Resistance, 3,100 ohms. Battery, 100 Callaud.

In the second series of experiments the transmitting apparatus was at Lille and the receiver at the Ministry of Telegraphs, rue de Grenelle. Experiment, January 19th: Half speed; Paris-Lille. Underground wire of 282 kilometres. Resistance, from 1,500 to 1,600 ohms. Experiment, January 20th: Paris-Lille, *viâ* Châlons, Bar-le-Duc, Nancy, Longuyon, Mézières, 770 kilometres, out of which 210 in 5mm. wire and 560 in 4mm. Resistance, about 6,900 ohms. The results of this second set of experiments were most successful, and the output of the steno-telegraphic apparatus proved to be very much greater than that of existing French telegraphs.

We have stated that, during each turn, the commutator with two sectors, for instance, allowed the transmission of two stenographic lines, corresponding to about 280 words per minute. But, on the other hand, an operator at the key-board can only work at the rate of 200 words. It would thus have been necessary to make use of two key-boards, and no contacts should be lost by the operators who would have to manipulate in turn and rhythmically. In reality, this is hardly possible, and an operator able to steno-

Digitized by Google

graph 200 words per minute on an ordinary key-board can only, when thus hampered by the rhythm, transmit a much lesser number. This naturally brings us to mention the recent improvements made by M. Cassagnes. These improvements consist in the adjunction to the steno-telegraphic system just described—and which is of the nature of *multiplex* telegraphy—of a mechanical perforator and of an electrical transmitter which gives it also the character of *automatic* telegraphy. Through the use of a perforator, the key-board no longer gives direct electric contacts, but produces mechanically a perforated tape on which the signs are represented by holes at their respective places. The perforating key-board standing thus quite

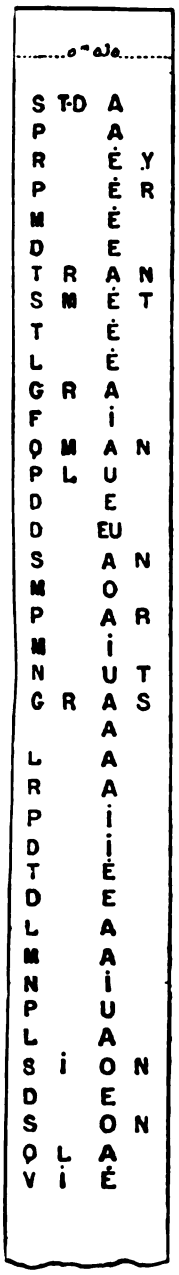

FIG. 4.—Slip produced by receiving instrument.

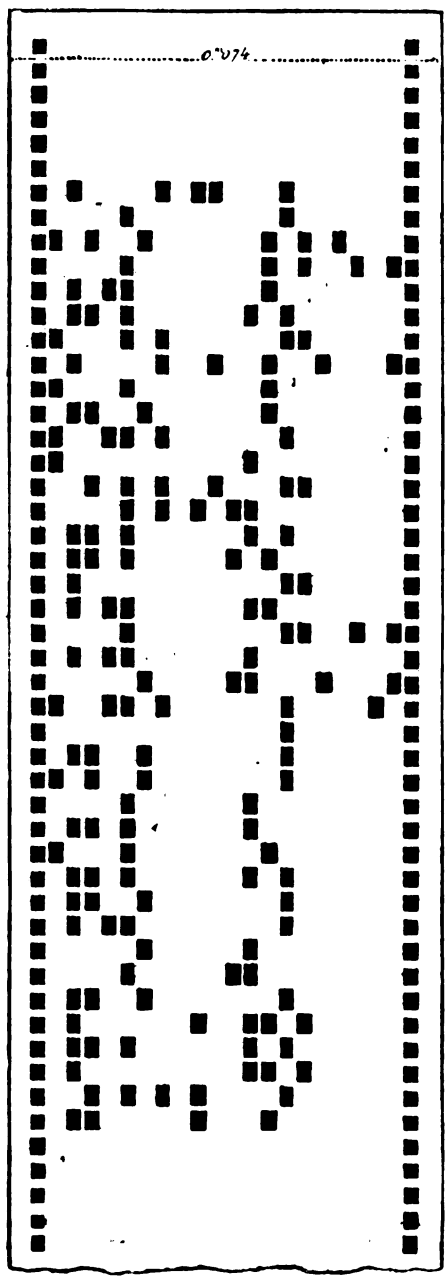

FIG. 3. Perforated slip.

independent of the rest of the steno-telegraphic system, the tape can be perforated at any speed, as when a correspondence is being copied or a speech stenographed. The perforated tape is then put in the transmitter and passed through at a speed regulated by the motion of the transmitting brush on its commutator. A set of springs successively establishes the contacts through the holes in each line of the perforated tape; and the currents, passing through the line wire and the relays, work the styles corresponding to the holes and print the stenographic signs on a line corresponding to that of the holes in the transmitting tape. The following speeds of transmission have been obtained by means of this automatic part of the system. 1. Up to 350 kilometres, 400 words per minute. 2. Up to 650 kilometres, 285 words per minute. 3. Up to 900 kilometres, 200 words per minute.

These numbers give the theoretical result, implying that there is no stoppage in the preparation of the tapes and their passage through the transmitter. It is also well understood that each sector can be used equally well for transmitting or for receiving, and that the above number of words represent those simultaneously sent in both directions, according to the wants of both stations.

Ordinarily phonetic orthography is employed; but, if desirable, grammatical orthography can be used, although, of course, at the cost of considerable reduction in speed. In Figs. 3 and 4 are shown respectively a perforated slip, and the corresponding slip of the receiver.

ELECTRIC LIGHTING IN THE TROPICS.*

BY W. H. FLEMING.

One of the chief difficulties that an engineer experiences who is called upon to instal a plant of any considerable size in tropical countries is the trouble of procuring any skilled labour for this particular class of work. Another difficulty is that he is so far from his base of operations—the factory—which will often lead him to depend upon himself in overcoming obstacles that arise from time to time as the work progresses. Language and the heat, as well as fevers, are minor affairs.

Electric lighting has already gained many warm adherents both in the East and West Indies, more especially in the former, where plants of considerable capacity have been in active operation for the past eight years. It is especially adapted for use in houses in warm climates, such as that of India, where the old-fashioned "punkah" is in daily and nightly use for cooling the rooms, accompanied with its attendant noise, as the "punkah wallah," a servant, pulls it backward and forward, causing the continual flickering of the lamps or gas. That system will, in time, I hope, give place to the noiseless motor fans and steady incandescents, thus enabling the Anglo-Indian to read and rest in comfort.

A central station plant that the writer was engaged upon lately in one of the chief cities of the West Indies would compare favourably in size and equipment with one situated in a city of a corresponding number of inhabitants in the United States. Alternating-current dynamos of a capacity of 4,500 16 candle-power lamps were employed for lighting the chief stores, theatres, and private houses, and 600 arc lights of 1,200 candle-power each lighted up the main streets and parks. It was at first intended to run a small plant in connection with the existing gasworks, more as an experiment than with a view to actual financial success; but in the space of six months the station was more than trebled from its original capacity. The people took to it from the start, paying cheerfully the prices that were demanded. To an indolent race it was a great boon. Money to them, it would appear, was of less account than the trouble and work called upon to go around and light up the different oil and gas lamps, since all the lights were switched on the different circuits at sunset. In the tropics, as is well known, there is no twilight. Darkness comes on within ten minutes of sundown, and the whole plant practically goes into operation at once.

The construction work on this particular plant was necessarily somewhat slow, as men unaccustomed to erect a 30 or 45 foot pole took their time to do so, in which operation they received the appreciation of the usual army of idlers. Poles suitable for carrying a number of circuits had to be imported from the United States, as well as the ornamental wooden columns for supporting the lamps in the parks and public squares. Poles of native growth could not be found straight enough, and even if of sufficient length were weak. Some poles could have been had from a tree called the ironwood tree. This wood, however, is of so close a grain and so very heavy that it was out of the question to use it. Many of the business streets were not more than from 20 to 30ft. across, including the sidewalks. Moreover, as curtains or awnings are stretched overhead from side to side by the owners of the stores to shelter and protect their goods from the sun's rays, it was impossible to erect a pole line down these streets. I found it better to run a 2in. iron piping up to the side of the houses every 150ft. to a point 6ft. above the coping stone, and then attaching to the top of this pipe a T, inserting in this T wooden cross arms, to which the insulators were attached in the usual manner. It must be borne in mind that the houses are not of very great height. Where this arrangement was impracticable, owing to the varying heights of the houses, I inserted strong iron brackets in the buildings, set in with cement and well painted with rust-proof paint.

* Read before the General Meeting of the American Institute of Electrical Engineers, Boston, Mass., May 21, 1890.

In India considerable care has to be exercised in putting up a pole-line. If you want your work to stand any length of time, the base of the poles for one-sixth of their length must be thoroughly well creosoted, to resist, as far as possible, the ravages of an insect, called the white ant, or "termite." These insects live on wood. They attack even the woodwork of the houses, and soon reduce the thickest timber to a mere shell. They live in trees and construct nests of great size, like small sugar casks, made of particles of gnawed wood, and cemented by a kind of gluten. They are so strongly attached to the branches that they cannot be shaken down even by violent storms. It is a good plan to paint the poles eight feet above the surface of the ground with good gas tar if obtainable. In these climates special attention should be given to protecting the working parts of arc lamps, owing to the fact that rain occurs only for about three months of the year; and to make up for this loss, the humidity of the atmosphere is remarkable. It is not at all infrequent to find early in the morning the bottom carbon holders full of water, unless provision is made for draining this off. During the hot season a breeze springs up between nine and ten o'clock in the morning, and the ground being dry, the dust is terrific. Insects of a large size—much more so than those found in the northern climates—bats and small birds attracted by the glare are found either in the globes or lying at the base of the lamp posts in large quantities every morning; and the wholesale slaughter that takes place nightly seems to have no effect in diminishing these pests. It was found better, therefore, on the arc service to give a man about 25 lamps to trim and clean per day; and the native entrusted with this work was held responsible, and if the lamps were found in a dirty condition he was fined, which usually had a good effect.

In the construction of station buildings one is guided much by the facilities for procuring stone, brick, or other suitable material in that particular locality. Galvanised iron is sometimes used for roofing, but more frequently roofs are constructed of a sun-baked clay tile, provision being made as is usual for an ordinary wire tower for distributing the various circuits. A point to be noted is that the engineer should construct his rain gutters for taking off the storm water at least double the size that is ordinarily allowed for temperate climates. Roofs and the outsides of the buildings are whitewashed.

To give an idea of the heat from the sun, I may mention that I had to replace considerable quantities of insulated wire after it had been up only a short time, the insulation in places sagging right away from the copper wire and finally dropping off. During the rainy season prevailing in the West Indies in the months of June, July, and August, and in the East Indies known by the name of the south-west monsoon, and prevailing from May to the latter part of August, electrical storms occur almost daily. They are often exceptional in violence, and much trouble and anxiety arise from possible damage to line, lamps, and dynamos, even though protected by good lightning arresters.

While a heavy storm was in progress one night last summer in the West Indies, I noticed when in the station a curious effect of a flash, that fused the lead strips on an ordinary saw-tooth arrester connected with one of the incandescent circuits. The strips were entirely destroyed or volatilised, and what was before a polished plate of brass, was now tarnished with a film of the lead vapour; and there was distinctly marked, as if photographed on the plate, a zig-zag streak, in all appearance like a photograph that had been taken of lightning. Engineers, during the prevailing season of storms, should take particular pains that their lines and machines are thoroughly well protected, and that the arresters have good earth connections.

A sad case came under my notice that happened at a temporary installation for illuminating a camp in Poonah, in the Bombay Presidency, with arc lamps in honour of a visit of an influential rajah. While the festivities were taking place in the evening, a heavy storm occurred. Lightning entered on the line—no provision had been made for diverting its course—and it destroyed the dynamo, besides killing the native oiler who just at that moment was engaged in filling up the oil cups on the bearings. He was either thrown or fell across the commutator end of the dynamo, as he was found in that position, his hands much burnt as well as his feet.

In the year 1877 the first commercial arc lamp was in use at the offices of the Bombay *Times*, and if I remember correctly it was the first light shown in the Indian Empire. From that date on the demand for lighting has been on the increase; but pretty nearly all the work has been confined to isolated work and small central stations, cotton mills, sugar and indigo plantations, Government buildings and large private dwelling houses. Places of business and offices do not require lighting, as business is conducted by the merchants only from seven o'clock in the morning till four in the afternoon. The inhabitants of hot climates necessarily spend much of their time out of doors and are fond of social gaiety. They have been famous for centuries for skill in illuminating; and this fact has added much to the popularity of arc and incandescent lamps, which, as is well known, particularly lend themselves to artistic illuminating purposes. From this knowledge, in the early part of 1885, I imagined that it would be a financial success to get together a travelling portable electric light plant, consisting of a vertical boiler, engine, and two dynamos, one an 8-arc light machine and the other a 100-light incandescent, both mounted on a stout frame which rested on a pair of trucks. This work was carried out, and I was kept actively employed for many months in going round to different large Indian estates and native palaces for the fêtes that attend the various religious and family ceremonies that the wealthy natives are fond of indulging in. Large sums of money are spent, and the festivities often last for a week or longer. It turned out to be, as I surmised it would, a regular "bonanza," until on one occasion in bringing the unwieldy contrivance down a steep hill, on one side of which was a ravine, it fell over; and it is needless to relate that the whole apparatus was seriously damaged. I found it would not pay to patch it up again, so, after stripping everything that was portable, I left the remainder to lie and rust in the tropical vegetation.

Owing to the high price of coal, which is a costly article in the tropics, ranging from $8 to $50 per ton delivered, it is well to employ the most efficient and economical engine for motive power, more especially for central-station work. In the station previously referred to we were running with high-speed compound condensing engines with satisfactory results. In many sugar plantations in the West Indies where the installations are of a comparatively small size, economy in this direction is not practised, as the amount of steam used is not missed, the boiler capacity on estates ranging from 100 horse-power to one at Cienfuegos, Cuba, of 2,500 horse-power. It behoves the engineer, however, who has charge of a plant to exercise considerable care and watchfulness over his native firemen. The natives as a rule, I have found, if treated with kindness and forbearance, show an aptitude in learning and taking hold that is often remarkable, more so than with some of their brethren of a lighter colour, who, because they have been taught how to start and stop a dynamo, or trim an arc lamp, give themselves all the airs of an expert in electrical matters, and have got beyond that stage when they are willing to be instructed, or to be obedient to orders—an unwillingness that sometimes leads to disastrous results.

The types of machines chiefly in use in the East Indies are those of English and French manufacturers, Siemens, Gramme, Silvertown and other well-known types. Those in use in the West Indies and South and Central America are generally of American make, and the market is not a small one. The great strides that both the foreign and home companies have made in the last two or three years in the supply and equipment of electrical plants for these distant lands, are very evident signs that this particular business is receiving great attention at the hands of local merchants, planters, and city or town officials, and that they are more and more influenced by the many advantages to be gained by the use of electric lighting. Planters find now that it is much to their gain in a financial way. In former years, for example, the facilities of shipping their produce were restricted, and the work was done in daylight and slowly. Now with weekly and almost daily sailings, it has become an absolute necessity that they should get their produce ready with the quickest despatch possible, and this they do by the aid of the electric light.

When an engineer is called upon to instal or take charge of an electric light plant, it will be well for him to insist pretty closely not only that all the materials specified in the estimates have been shipped, but that every class of tool requisite for constructional work is included. Much time is lost and much trouble is made when you find that your outfit does not include "climbing spurs" or draw vises and other important articles. I have known engineers who have had expensive testing sets, Wheatstone bridges, reflecting galvanometers and other delicate instruments sent out with them, and then found that they had few or any tools to work with, and that the nearest hardware store was many miles away through a rough country; and even then, the store when reached did not contain the requisite goods, there having been no stock kept because there was no demand made for them. Spare armatures, complete sets of arc lamp apparatus, as well as duplicate parts of dynamos, spare brasses and gear for engines and tubes for boilers, should always be included, and it should be seen that they are shipped.

Apart from the vicissitudes incidental to life in the tropics, there is, I think, always a satisfaction and pleasure in the successful completion of an installation, knowing as one does that it is a potent factor in the greater civilisation of those countries, demonstrating to the inhabitants, who have heretofore depended on artificial illumination of the same primitive character and manner as their forefathers used through ages past, what science, aided by her lieutenants, "pluck and energy," can accomplish.

THE LANE FOX PATENTS.

A meeting was held at the offices of the Lane Fox Electrical Company on the 1st inst.; Mr. Cobden Saunderson in the chair. Among those who were present were Mr. St. G. Lane Fox, Mr. C. A. Stephenson, Mr. W. Grove, Mr. Sidney Morse, Mr. B. Drake, Mr. R. S. Erskine, Mr. C. F. Cooper (Messrs. Paterson and Cooper), Mr. F. Gripper (Messrs. Edmundson), Mr. Stepney Rawson, and Mr. A. P. Trotter.

The CHAIRMAN commenced by a *résumé* of the situation of the patents of Mr. Lane Fox. These patents had been transferred to the British Electric Light Company, who did nothing with them, and whose business was transferred to the Anglo-American Brush Company. This Company was principally interested in arc lighting, and did not bring incandescent lighting to the front, as they wished to push their arc lighting specialities. As soon as the numerous sub-companies were formed, a complicated tangle of litigation followed, and it was impossible to take any proceedings to work the patents. It was not until late last year, when the litigation between the Anglo-American Brush Company and the Edison Swan Company was concluded, that the patents were ultimately transferred to Mr. Lane Fox, the two companies reserving its licences. The Lane Fox Company was then formed. The patents, as patents, were in abeyance for several years; but the system described by the patents was adopted generally wherever incandescent lighting has been used. The object of the Company was to be paid for the use of the system. The Chairman then referred to the published reports and opinions of various authorities, and an analysis of the patents of Mr. Lane Fox and of Mr. Edison, and to circulars which had been sent to the trade making offers as to royalties. Several different methods were suggested. For undertaking companies it was proposed to make a charge based on the Board of Trade units supplied to consumers. For private installations the charge would be based on the number of lamps; 1s. 6d. per 16 candle-power lamp being charged for private houses, and 2s 6d. for public buildings, such as clubs, hotels, offices, &c. It was suggested that contractors might collect the royalties from the customers who had bought plant from them, and if the contractor negotiated such payment a discount of 10 per cent. would be allowed to the contractor. In conclusion, he invited discussion, criticism, advice, and co-operation in whatever was found to be reasonable.

Mr. C. F. COOPER asked for information as to what kind of installations were meant?

To which the CHAIRMAN replied: All which include the use of accumulators which involve the patent.

Mr. COOPER asked what was claimed.

Mr. LANE FOX: The patent covers the system of constant potential where accumulators are used. At the date of the patent the idea of constant potential was unknown. He had had many arguments with Mr. Preece, Sir W. Siemens, Mr. Spottiswoode, and others; and at that time the idea was inconceivable to them. They all thought that the current would go by the shortest course through the first lamp. They could not conceive the idea that the mains would offer a very small resistance. The Edison system, which was said to embody the discovery of practical distribution of the electric light, turned out to be merely a method of regulating lamps arranged in series. He spoke always of "the current."

Mr. COOPER: Does not the patent assume that there was no method of regulating, such as we have in the compound machine?

Mr. LANE FOX: The patent assumes no machine.

Mr. COOPER: In many small installations, accumulators are not used, there is simply a compound machine.

Mr. LANE FOX: I described the idea of a shunt for regulating, but I do not now claim it, and where regulation is achieved by other means we do not claim it.

Mr. COOPER: Where there is a small plant, in which you charge the accumulators in the morning, and you leave them to run the lamps at night, do you claim that?

Mr. LANE FOX: Certainly; there are broad claims in the patent, but they are narrowed down to batteries by the disclaimers.

Mr. COOPER: The Patent 3,988**, as it stands at the present moment, appears to describe accumulators acting as regulators while the dynamo is going—is not that merely as a regulator?

Mr. LANE FOX: It is stated "The supply will be available after." A regulator and a reservoir are the same thing. At first, the exactly opposite view was taken, and it was suggested that it referred only to an installation where the lamps vary in number.

Mr. STEPNEY RAWSON: In 1883 it was said that batteries would not act as regulators. Will there be no claim for royalties where no accumulators are used?

The CHAIRMAN: No, that is disclaimed. It is only where accumulators are used as regulators or as reservoirs.

Mr. GRIPPER: You do not claim parallel distribution only, or the use of accumulators, but the combination?

The CHAIRMAN: That is so.

The question of the validity of the patent being raised,

Mr. SIDNEY MORSE said that they could not settle the validity of the patent at this meeting.

Mr. A. CAMPBELL SWINTON presumed that they might pay a small royalty if they had little doubt, and pay more if they had a great doubt.

Mr. SIDNEY MORSE: Certainly, you should pay nothing if you do not believe in the validity of the patent.

Mr. SWINTON asked how the opinions which had been republished had been obtained—some appeared to be statutory declarations, and began without any preamble.

Mr. LANE FOX replied that they were given in the action against the Edison Company by the Brush Company. The result was a compromise. The case was for the use of parallel distribution at the Athenæum Club, in 1886.

Mr. SWINTON said that he had been given to understand that one gentleman repudiated the construction which had been put upon his statement.

The CHAIRMAN: We put no construction.

In reply to an invitation for some suggestions,

Mr. COOPER said that it was not a sufficiently representative meeting to enable anything to be settled. He reserved anything he had to say, he merely came to learn.

Mr. GRIPPER said that he too had only come for information.

Mr. SWINTON asked whether, in a case where there was a large number of lamps, and a small accumulator capable of supplying only a few of them, the royalty would be charged for the lamps.

The CHAIRMAN replied that an attempt had been made to meet different cases by different methods.

Mr. ERSKINE pointed out that, if a charge was made on the revenue of a central station, part of the revenue goes to the buildings and engines, and these had nothing to do with the patent.

Mr. SIDNEY MORSE: You might shave your revenue down to nothing in that way. Buildings and such charges occur in all businesses.

Mr. ERSKINE: Under those conditions we would rather not put up such plant.

Mr. SIDNEY MORSE: But does not this come, in your case, to only £300 a year,—only $\frac{1}{10}$th of the maximum charge per unit for two years?

Mr. LANE FOX: Special terms are offered to those who will come to an arrangement now. We do not pledge ourselves to make the same terms hereafter to the rest of the trade.

Mr. SWINTON: Do you expect the consumers to pay? Do you count on having a remedy against the consumer, or against the contractor?

Mr. SIDNEY MORSE: Both.

Mr. SWINTON: Does not this offering of a discount amount to a bribe?

Mr. SIDNEY MORSE: Such discounts are common in any selling transaction.

After a general discussion, during which no definite offer was made or entertained, the meeting separated.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 20, 1890.

The Halpin-Savage Torpedo Boat.—This electric automobile torpedo boat seems to be reaching a stage at which its general adoption by the Governments of the world is probable. Its main peculiarity as distinguished from other vessels of the sort is an arrangement by which the torpedo is fired from the boat after it has come in contact with the netting surrounding a vessel, and is fired downward, being retained by a chain, so that its course is semicircular, and it thus explodes directly under or alongside of the vessel attacked. The boat is submerged near the surface of the water, and is guided by incandescent lights, which show from the rear only. The boat is driven by storage batteries, and carries with it five miles of wire for guiding purposes. The screw propeller makes as many as 2,000 revolutions per minute, and gives the boat considerable speed. It is in many respects an advance upon anything that we have had upon this side of the water thus far.

Electric Traction for Railways.—The electrical engineers of America having, as they believe, conquered the street horse-car, and feeling confident of their victory over the cable-road as well, are turning serious attention to the problem of applying electricity to regular railroad work, and have previously noticed the splendid researches of Mr. O. T. Crosby in this direction, and other investigations, showing the direction in which the problem is gradually developing. Dr. Louis Bell, the editor of *The Electrical World*, read before the Scranton Science Club last evening a long and elaborate Paper upon the history of electrical traction in general, confining himself in the main to that part of the work which has already been done, and is firmly established in electrical history. His lecture was therefore mainly interesting to electricians because it gave the flat-footed opinion of so eminent an authority that electric traction is certain in the near future to replace the steam locomotive. Dr. Bell said:—"I do not hesitate to say, and I say it deliberately, that to operate an ordinary railroad train by an electric locomotive is a far simpler problem electrically and mechanically than the operation of street cars under ordinary conditions of City traffic. The slow speed necessary for street cars is a disadvantage in that it

Digitized by Google

compels us to gear down the motor. In running at railway speed no such difficulty is encountered, and the obnoxious gearing may be dispensed with entirely. Nor is there any practical difficulty in building motors large enough to do the work. I do not think there is a prominent electric company to-day that would hesitate to take an order for a 500 horse-power machine and guarantee its performance. I certainly know of several that would be glad of the chance, and would accomplish the task successfully. Neither is there any difficulty in conveying the current to any of these large motors moving at railway speeds. In other words, the question is simply one of economy. As to this, I consider it to have been absolutely demonstrated that electricity can profitably replace steam in this field. The principal advantage that we should gain by using electric motors supplied from a central station instead of the present steam locomotive would be a much more economical use of coal. This is due, of course, to the vastly superior efficiency of stationary compound engines as compared with the locomotive of to day or of any other day, and also to the fact that the electric motor does not have to carry with it its coal and water, and can be kept clean, which a locomotive cannot." Dr. Bell also pointed out the magnificent possibilities of economy in the use of water power along the many roads of this country that follow streams upon which hundreds of thousands of horse-power are constantly going to waste. This power by the adoption of electric railroading could be turned into available traction.

The Association of Railway Telegraph Superintendents.—This Association held its ninth annual meeting at Niagara Falls on June 18th and 19th. Papers were read by Robert Stewart, superintendent of the Central Railroad of New Jersey, on the "History and Development of the Block System." Mr. Stewart was the first to introduce this system in America, and has been foremost in the development of it in this country, and he gave a very complete account of all the different systems in use in this country, with a history of the development of each. Mr. Charles Selden read a Paper upon the "Increased Adhesion between the Wheels of the Locomotive and the Track caused by the Passage of a Current of Electricity." His conclusions followed those of Mr. Elias E. Ries, and Mr. Selden is firmly convinced that an important discovery has been made in this field which will increase the tractive power of locomotives by something like 25 per cent. Mr. Selden's statements, however, were questioned by Mr. Nicholls, whereupon a model motor and track were introduced to prove the assertions of Mr. Ries. The experiments made satisfied those present of the correctness of Mr. Selden's conclusions. Mr. W. F. Taylor followed with a Paper on "Lighting at Wrecks," and gave a description of the electric light car used by the Pennsylvania Railroad to illuminate the scenes of accidents and to facilitate clearing the track after trouble. Other Papers were—by Mr. B. Leonard, on "Electric Lighting in Railway Service;" by Mr. George C. Kinsman, on "Train Despatching, its Uses and Abuses;" and by Prof. H. S. Pritchatt, of Washington University, St. Louis, on "Correct Time and How shall we Maintain it."

CORRESPONDENCE.

PRIMARY BATTERIES FOR LIGHTING PURPOSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The article in your number of June 27th about primary batteries shows me that your paper sides with the majority in condemning primary batteries for lighting purposes. Let us look into the difficulties you raise, and see if they are really insuperable.

First, as to the cost—the all-important point. It is the fashion among electrical engineers of the day to say that primary batteries *must* dissolve or consume 20 grains of zinc per ampere-hour; and that, therefore, since zinc is more expensive than coal, primary batteries *must* be more expensive than steam-engines. To begin with, although something must be consumed to produce current by chemical means, it is by no means conclusively proved that that something need of necessity be zinc; neither has it been proved that zinc is the most economical thing that can be used. However, let us take it for granted that we must use zinc, merely for the sake of argument, and let us see what the consumption of zinc would cost, provided there was no waste. The market price of Silesian spelter, according to the *Economist* of June 27th, was £23 per ton; this works out at about 2½d. per pound. Upon this basis it would be calculating on the safe side to take zinc moulded to given sizes at 1s. per pound. Then 20 grains of zinc consumed to produce one ampere-hour of current, we get 384 ampere-hours of current for 1s., as far as the consumption of zinc is concerned. When we come to think that lamps of all tensions, from five volts upwards, are now being made to take but half an ampere of current, we can see that the consumption of zinc is not a very formidable item in the cost of working a primary battery, being about 1s. per day of seven hours for 100 lamps, taking half an ampere of current. Now as to the solution used, how much acid does it take to consume 20 grains of zinc? My answer is, that it takes comparatively little.

I think if we come to consider the reason why the thing has not been economical so far from a chemical point of view, we shall find that it is because too great an excess of acid is put into each cell at starting, and that therefore the action set up is more rapid than is necessary, giving rise to the evolution of an unnecessary amount of hydrogen gas and the consequent necessity for the introduction of a very powerful depolariser. Now let us investigate how far this point of the economy of a battery has so far been understood and compensated for.

So far primary batteries exist in two forms, namely, the single and the two fluid cell. What are the defects of both, and how can they be remedied? First take the case of the single-fluid cell; in this an active fluid is used to act upon the zinc, and as it is found that the cell polarises we introduce an oxidising agent which is supposed to take up the hydrogen formed. So it does, part of it; but a portion of the depolariser acts on the zinc forming more hydrogen, since it probably has a greater affinity for zinc than for hydrogen; and, therefore, it has been found that the action of a single-fluid cell is spasmodic, and that the only way to prevent the cell getting exhausted in a very short time is to perpetually refresh the solution, which entails the consumption of a very large quantity of solution and zinc. Next, let us take the case of the two-fluid cell. In this case we use a dilute solution to act upon the zinc, and a powerful depolariser surrounding the negative element separating the fluids by means of a porous division of some kind; here a better result can be expected, as the too rapid action of the depolariser is restrained by the porous division; but the mistake in this case is that the porous division is in itself a non-conductor of electricity, and the result of the cell is therefore limited by the internal resistance. A cell must therefore be invented which slowly supplies the depolarising fluid, and has at the same time a low internal resistance. This is not impossible, as I propose to show in a very short time.

The last difficulty which your article raises is the question of skilled labour. I flatter myself that my own or any other very ordinary human intellect is good enough to devise an arrangement to automatically supply a liquid at a given rate from a cistern filled once a week, month, or even a longer period, according to the size of cistern and amount of work required. In towns, this cistern could be mounted over a battery in a cellar under the pavement and supplied through a port in the pavement in the same sort of way as our coals are now, thus dispensing with any such phenomenal person as the domestic servant mentioned in your article. I think, if you consider the foregoing points, you will come to the conclusion that a primary battery fit for lighting purposes, though perhaps at present unknown and at first sight an impossible thing commercially, is still a possible thing. But I venture to say that it will be invented by a chemist, and not by a steam engineer converted into an electrician.

In conclusion, let me say that I wish I had the honour to be that man. It must also be borne in mind that the chemical was the first way of producing electricity, and I fancy it will finally triumph over steam.—Yours, &c., ELECTROMANIAC.

LEGAL INTELLIGENCE.

Gorman v. Brighton and Hove Electric Light Company (Limited).

In the Queen's Bench Division of the High Court of Justice, on Saturday, the case of Gorman v. Brighton and Hove Electric Light Company was concluded before Mr. Justice Denman, Mr. Justice Charles, and Mr. Justice Vaughan Williams, sitting as a Divisional Court. This was a motion by the defendants for a new trial on the grounds of misreception of evidence, and that damages were excessive.

Mr. Pyke appeared for the defendants in support of the motion, while Mr. Chapman opposed it on behalf of the plaintiff.

Mr. PYKE, in supporting the motion, said the action was brought by the plaintiff, sueing for herself and six children, to recover damages for the loss of her husband. The husband, who was 32 years of age at the time of his death, was a night watchman in the employ of a brewery company at Brighton, and in receipt of 22s. per week. He was found dead on the roof of a house, having apparently been killed by an electric shock. The question of damages was tried before the Under-Sheriff and a jury, who awarded the plaintiff £800, being £200 for herself and £100 for each of the six children. He (the learned counsel) submitted that the amount of damages was excessive. On behalf of the plaintiff, an actuary was called to show that an annuity for a man in the position of the deceased for an amount representing what he earned would cost £1,090. He submitted that such evidence ought not to have been admitted, as it was not the proper basis for the jury to have assessed the damages upon. There were many contingencies to consider—the man might not have remained in continuous employment, and so on.

Mr. JUSTICE DENMAN said it seemed to him that the damages might be regarded as excessive in the case of the children rather than of the widow.

Mr. PYKE remarked that he had calculated that at the outside the jury should not award the widow more than £150, or give more than £50 each to the children, making in all £450.

Mr. JUSTICE DENMAN thought that the case was one that might be compromised. There had been an omission apparently to consider the position of the widow.

Mr. CHAPMAN said all the matters were left to the jury by the Under-Sheriff. As to a compromise, the difficulty was that his client had fixed a sum below which he could not go, and his learned friend could not assent to that.

Mr. JUSTICE DENMAN mentioned privately a sum which he and his learned brethren thought plaintiff ought to accept.

Mr. CHAPMAN said he could not accept the proposal until the solicitor had communicated with the plaintiff.

Subsequently Mr. CHAPMAN said he had received an intimation from his client that she was prepared to take £550, which was £50 in excess of the amount suggested by their lordships. The extra £50 was added to clear her of any possible costs that might arise between her and her solicitor.

Mr. PYKE said the defendants could not undertake to pay more than £500. Of course, if the jury had in the first place given that amount the plaintiff could not have asked for £50 for costs between her solicitor and herself. She had already had taxed costs.

Mr. JUSTICE DENMAN said the Court could not screw the defendants up to give the plaintiff more than £500, but they thought that the defendants should pay the costs of the motion for a new trial.

Mr. PYKE said the defendants were willing to do that.

The motion for a new trial was accordingly refused with costs, the damages being reduced to £500.

The Whitecross Company v. The Credit Lyonnais.

This case, which was recently tried before Mr. Justice Smith and a special jury, and resulted in a verdict for the plaintiffs for £1,446, was argued on Friday last before the Divisional Court, consisting of Justices Denman, Charles, and Vaughan Williams, on a motion for a new trial.

Mr. Gully, Q.C., and Mr. Abrahams represented the applicants; Mr. R. T. Reid, Q.C., and Mr. Hollams for the respondents.

The claim was for damages in relation to a contract entered into between the plaintiff Company and the Spanish Government for galvanised iron wire for telegraphic purposes, the allegation being that the defendants had undertaken to act as plaintiffs' agents in Madrid, and by their neglect allowed a firm of Hamilton and Co., through whom the contract was originally made, to obtain payment from the Spanish Government, which the said Hamilton and Co. did not hand over to the plaintiffs. The defendants alleged, on the contrary, that they only undertook to act as bankers, and were not responsible for the loss the plaintiffs had sustained.

Mr. JUSTICE DENMAN held that the judge at the trial was right in leaving the questions he did to the jury instead of interpreting the contract himself as a question of law, though this was not very material, as the finding of the jury was in accordance with the interpretation which the judge ought to have put upon the correspondence had he deemed it right to do so. Neither did he think the verdict could be attacked on the ground that the damages were excessive or too remote.

Mr. JUSTICE CHARLES concurred in the result, though he thought the question should not have been left to the jury.

Mr. JUSTICE WILLIAMS agreed entirely with Mr. Justice Denman.

The motion was dismissed with costs, but it was intimated that there would be a further appeal; execution was stayed for 14 days.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

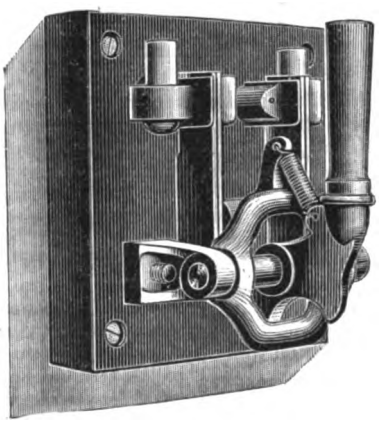
APPOINTMENTS VACANT.—The Guardians of the poor of the Fulham Union, having in contemplation the adoption of the electric light for the workhouse, infirmary, and other premises of the Union situate in the Fulham Palace-road, Hammersmith, announce that they will be glad to receive offers from practical engineers, thoroughly experienced in electric lighting, but totally unconnected with any particular company or system, who would be willing to survey the Union premises and advise the Guardians as to the best and cheapest way of carrying out the work they have in view. Full particulars will be found in our advertising columns.

FOR SALE.—Particulars are given on page xv. of advertisements of an electric light station to be disposed of by the Alliance and Dublin Gas Consumers' Company.

MESSRS. LAURENCE, SCOTT, AND CO. (LIMITED).—We are asked to notify that the style under which Messrs. Laurence, Paris, and Scott (Limited) has previously traded, has been altered to Laurence, Scott, and Co. (Limited).

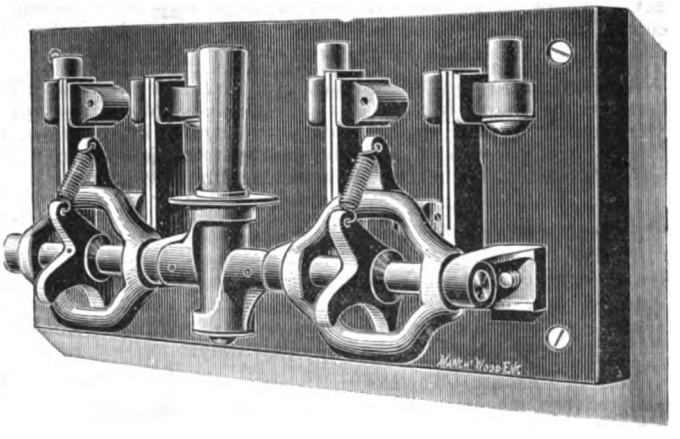
A NEW STORAGE BATTERY.—Messrs. Shippey Brothers have on view a new type of storage battery called the "Standard." It is specially constructed for traction purposes and boat propulsion. The elements are light in weight, and are easily handled; the plates, instead of being vertical as is usual, are placed horizontally, separated by china discs. At present only one size and type will be made, viz, 17 plate cells, 200 ampere-hour capacity; size, $6\frac{1}{2} \times 6 \times 11$. The inventors do not limit the rate of charge between 10 to 100 or even the discharge, provided the cell does not fall below 1·7.

MESSRS. DORMAN AND SMITH'S NEW SWITCH.—We illustrate a single-pole and a double-pole switch now being manufactured by



Single-Pole Switch.

Messrs. Dorman and Smith. These switches have a sudden release, double break, and large spring contact surfaces. They are strongly made, and, as will be seen by the illustrations, bear evidence of



Double-Pole Switch.

having originated in an engineer's shop. These switches are made in several sizes in both the single-pole and double-pole types.

Digitized by Google

THE PAISTE SWITCH.—We illustrate below a novel form of switch, designed and patented by Mr. H. T. Paiste, of Philadelphia, U.S.A., for the manufacture and sale of which Mr. A. Reyrolle, of Union-mews, London, W., has recently secured the European rights. The switch has met with much success in America, where we are informed that not less than 100,000 are in use by the leading companies, including the Edison, Sawyer-Mann, Westinghouse, and Thomson-Houston. Many of the companies speak of the switch in terms of the highest praise. The following brief description will show the design of the switch:—Two plates (made from sheet brass), one U-shaped, the other being straight, are used. These are mounted on a base of non-conducting material. The binding screw on the U-shaped plate is the terminal of one circuit wire, and the screw on the straight plate the terminal of the other. Two arms, A and D, are hinged to a spindle, the bearing of which is located in the centre of the U-shaped plate. A spring joins the end of the two arms, and keeps the arm A pressing firmly against the straight plate, as well as the arm D against the U-shaped plate. The circuit is completed as the arm A joins the U-shaped plate, and the straight plate, through its spindle and the arm D, also at its point.

To break circuit the spindle is turned (by means of the handle screwed into its centre) to the right a quarter turn, by which motion the arm A slides along the straight plate (cleaning it) until B is reached (while the arm A is sliding along the straight plate it is lengthening the spring), at which point the straight plate becomes the tangent of a circle, of which the arm A (hinged on the spindle) becomes the radius. As soon as the straight plate becomes the tangent the arm A flies rapidly to C, when the circuit is broken. What arc-ing there is is on the back of the arm A, and not on the face, where electrical contact is made. The circuit is completed by a like movement, the arm D coming to rest at A. It is claimed by the inventor that each time the switch is used better contact is secured, as the arm seats itself in the straight plate, like a hammer blow. The switch is manufactured in various sizes, mounted on china, with cover and handle of same material.

MESSRS. SHAW AND CONNOLLY.—This firm are inviting tenders for the various works required in the erection of an electric cable manufactory at Newton Heath, as an extension to their present works.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.—This Company have taken premises at 56, Queen Victoria-street, London, E.C., where they have on view a large display of seamless copper tubes and cylinders of all sizes up to 18 inches in diameter.

TECHNICAL AND GENERAL NEWS AGENCY.—We were in error last week in announcing that this agency was established to supply "cuttings." We understand that the agency has been formed to furnish "reliable and original matter only obtainable through the agency's own connections earlier than through other sources."

INTERNATIONAL EXHIBITION OF MINING AND METALLURGY.—This Exhibition is announced to be opened at the Crystal Palace on July 16th. The New South Wales Government have taken 15,000 feet of of space, and South Australia, Western Australia, Tasmania, New Zealand, Victoria, and Queensland, will be unofficially represented, and several foreign Governments will participate officially. The machinery hall will be lighted electrically.

POSTAL REFORM.—The Postmaster-General is reported to have adopted the suggestion that the public should be allowed to post circulars, price-lists, and other documents not being of the nature of a letter in open envelopes at the book post rate; and that the Postmaster-General has also recommended the Treasury to permit any person to provide and transmit through the inland post a card bearing a half-penny adhesive stamp, such card to be the same size as the present post-card.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

June 16, 1890.

9,261. E. T. HEADECH. London. A new or improved electric arc lamp.

9,263. J. DRUMMOND. Manchester. Improvements in electric cut-outs and switches or other circuit breakers (R. O. G. Drummond and D. A. Bremner, South Africa).

9,274. P. H. WILLIAMS. Surrey. Utilising the waste or other water power of rivers, canals, tides, &c., &c., for electrical or other purposes by constructing or erecting lock, shute or other weirs, with hollow iron piers and foundations or casings upon iron screw or ordinary piles, and filling with concrete, &c., to carry water wheels and encased dynamo water wheels of any kind, or by floating dynamos on such dynamo water wheels.

9,275. P. H. WILLIAMS. Egham. Constructing water wheels of any form, and providing or utilising space in the interior for enclosing or attaching dynamos of any kind, or attaching encased dynamos to water wheels of any kind or to their spindles or shafts, or floating dynamos.

9,284. W. H. SCOTT and LAURENCE, PARIS AND SCOTT (LIMITED). Norwich. Switches for making and breaking electric circuits.

9,289. C. E. NICHOLS. London. Improvements in electric motors.

June 17, 1890.

9330. W. H. DOWLAND and W. MILLS. London. Improvements in the electrolysis of chlorides, and apparatus therefor.

9343. R. M. HAGUE. Newbury. A new and improved flexible-jointed pipe for fluids, gases, &c., and for insulation of electric or other wires.

9357. A. BARKER. London. Improvements in switches for electric glow lamps.

9361. T. L. WILLSON. London. Improvements in electric reduction of metals, and in apparatus therefor.

9395. O. ROMANZE. Of and on behalf of the firm of Romanze and Weise and F. W. White, London. Improvements in electrical apparatus for the production of rotary motion.

June 18, 1890.

9,429. E. BAINES. Huddersfield. An improved insulator for telegraphic or other purposes.

June 20, 1890.

9,602. SIEMENS BROS. and Co., Limited. London. Improvements in the distribution of electrical energy (Siemens and Halske, Germany).

COMPANIES' MEETINGS & REPORTS.

The West African Telegraph Company (Limited).

The fifth ordinary general meeting of the West African Telegraph Company (Limited) was held yesterday at Winchester House, 50, Old Broad-street, E.C.; Sir John Pender, K.C.M.G., presiding.

The SECRETARY (Mr. William Payton) read the notice convening the meeting and the minutes of the previous meeting, the latter being afterwards approved and signed as correctly entered.

The report of the Directors and statement of accounts (the former of which was given in our last issue) were taken as read.

The CHAIRMAN: Gentlemen, before I make any general remarks, I wish, as this is practically the second, or what I would call consolidating, meeting of this Company for the future, I should like to put before you a few figures, which will always be valuable to refer to at any future time. It will be seen on reference to the accounts in your hands that they have been arranged somewhat differently from those submitted in previous years. I think you will find the accounts in the new form to be

Digitized by Google

clearer and more convenient. The alteration has necessitated the charging of several items under different headings from those shown in 1888. It would, therefore, be unsatisfactory to compare the individual items and show the net increases and decreases, more especially as we have considerably augmented several of the stations for the joint working arrangement with the South African and other Companies and the new cable between Bonny and Principé. I will, however, show you the net result of the year's working to December, 1889, as compared with the previous year. The gross revenue for the year ending December, 1889, amounted to £64,661, as against in 1888 £55,315, or an increase of £9,346. This increase is almost entirely derived from traffic exchanged with South Africa. Communication between this Company's line and Cape Town was established on June 4th, so that in the past year's accounts we have had the benefit of this new traffic for only seven months. As the South African traffic is worked under a joint purse agreement between the Eastern, the Eastern and South African, the Brazilian Submarine, the Spanish National, and this Company, as long as the communication is maintained by either coast of Africa, our revenues are secured. The amount brought forward from last account amounted to £4,878. 4s. 8d., against in 1888 £1,215. 9s. 11d., or an increase of £3,662. 14s. 9d. The total expenses for 1889 amounted to £21,155. 9s. 8d., in 1888 £20,016. 0s. 7d., increase £1,139. 9s. 1d. This is almost entirely due to the causes just mentioned. The hire of cable-repairing ships, £1,780. 3s. 1d., is charged in the current revenue account, and the balance of preliminary expenses, £750, is written off. A fair amount has been written off for depreciation of cable stock. The net result of 1888, after providing for expenses, interest, and sinking fund for the redemption of the Five per Cent. Debentures, was a dividend at the rate of 2½ per cent. per annum ; £5,000 to repairs and renewals account, and £4,878. 4s. 8d. carried forward. This time we declare a dividend at the rate of 5 per cent. for the year, charge repairs and renewals to revenue account, and carry to general reserve fund the sum of £16,145. 11s. The balance standing to the credit of repairs and renewals account, £3,074. 2s. 5d., has been carried to general reserve fund, so that with interest on investments added, the general reserve fund amounts to £19,712. 18s., which, as will be seen from abstract C of the accounts, is fully invested in first-class securities.

Now, gentlemen, that puts your accounts in a very satisfactory position, and I think it redeems every promise that I made to you when I had the pleasure of addressing you twelve months ago. At the first meeting in 1887 there was no dividend at all, in 1888 we paid 1½ per cent., and in 1889, when the Board was reconstructed, the dividend was 2½ per cent. That was when I addressed you last, and I said that the combination that was formed led me to believe that the result would be a very considerable increase in the dividend of this Company ; that we should tap to some extent the Cape traffic, and that the joint purse formed would be such as to give this Company a fair proportion of that traffic. The outcome has been that we shall declare to-day a dividend of 5 per cent., as against 2½ last year. I may say, further, that this Company is, as I foreshadowed, on the rails, running a very favourable race alongside the other submarine companies, and I believe will play a very important part in the future of submarine telegraphy. If the Dark Continent is to be opened up we shall be prepared to lead, or to follow, as it may be, in the interests of those who open up that country. At all events we are ahead as pioneers, and we are prepared to do our part in that important development. I may mention, with regard to the Conference which has just been held at Paris, of all the submarine cable companies and all the land line companies of the different countries, that the result has been, I believe, that the cable companies hold a higher position to-day in the scale of telegraphic communication than they have ever done at any period of their history. It will be the pride of the Chairmen of all these respective companies to maintain that position. We stand high in the estimation of the public because we do our work well, and we stand well with the European Governments because they appreciate the work which we do. We are, on the whole, fairly treated ; yet at the same time the tendency is always towards reductions of rates, and we have to take our part in these reductions as well as the Governments. It must not be forgotten, however, that reductions very often lead to increased traffic ; and I hope whenever a reduction is made by any one Conference that the telegraphing public will so take advantage of it that by the time another comes round we shall recoup ourselves any loss that may be sustained. With these remarks I beg to move :—

"That the report and accounts for the year ended December 31, 1889, submitted to this meeting be, and they are hereby, received and adopted, and that a dividend be declared payable on and after this date of 6s. 6d. per share, free of income-tax, making with the interim dividend already paid, a total distribution for the year of 5 per cent."

Sir JAMES ANDERSON seconded the motion.

Mr. S. W. KORLLE said that it appeared from the prospectus that they had two subsidies—one of £42,000 and another of £12,000. What was the reason that the amount figured in the accounts at only £43,000 odd ?

The CHAIRMAN : The Portuguese is a guarantee—the French subsidy is a practical subsidy. The Portuguese undertake to make up a certain number of words which they pay upon, and that is more or less a fluctuating figure. It is a very courageous thing on the part of the Portuguese Government to guarantee a very large traffic of that kind, and, if that traffic should grow, to wipe out the guarantee altogether, which would show that the Company was depending upon trade traffic rather than upon Government protection.

The resolution was carried unanimously.

Sir JAMES ANDERSON moved and Sir HENRY MANCE seconded :

"That Sir John Pender, K.C.M.G., and Robert Kaye Gray, Esq., be, and they are, hereby, re-elected Directors of the Company."

The motion was carried unanimously

The CHAIRMAN : I am very much obliged to you for the honour of re-electing me to my seat on the Board of this Company. I am extremely pleased to see that we have laid a good solid foundation, and that year by year we have every reason to believe we shall erect upon that foundation a very handsome structure. The fact of myself and Mr. Robert Kaye Gray sitting on the same Board is good evidence of what I call union among telegraph companies ; and, as we all know, union is strength. I am very pleased to sit at the same table as Mr. Gray in promoting what we have at heart, the advancement of submarine telegraphy.

The CHAIRMAN next moved, and Sir HENRY MANCE seconded,

"That the appointment of John Denison Pender, Esq., as a Director of the Company be, and it is hereby, confirmed."

The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., having been re-elected,

A cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN, in returning thanks, said that he believed that the Board, as at present constituted, embraced all the elements which ought to make the Company a success. They were all men experienced in submarine cable work, and would be able to make this new Company a strong link in the great chain of the submarine telegraph system.

The proceedings then terminated.

The Electrical Engineering Company of Ireland.

The first statutory meeting of this Company was held on Saturday last at the office of the Company, Dawson-street, Dublin ; Sir Howard Grubb, F.R.S., presiding.

Mr. A. A. DAVIS, secretary of the Company, read the notice convening the meeting.

The CHAIRMAN said : This meeting has been called in conformity with the Limited Liabilities Companies Act, which requires a meeting to be held within four months of the date of registration. The Company was registered on March 5, 1890. The prospectuses were issued to the public on the 8th, and as a result 6,800 £2 shares were allotted to the public and vendors. At this early period of our existence, I suppose I will not be expected to make any detailed statements as to the work done by, or the future prospects of, the Company. I may mention, however, that although we can hardly be supposed to have fairly started and have not as yet got to work in the new premises which we have secured, and which we hope you will approve of, we have obtained some good contracts ; and the great number of estimates which we have been asked to furnish not only give good promise for the future, but show very clearly that the establishment of such a Company as this has become a necessity in Dublin. It must be remembered, however, that while there is little doubt that electric lighting will in time find its way into extensive use in this city, there are many causes which just at present check its development. The acceptance of many of the estimates applied for has been made contingent on the starting of the general electric lighting scheme proposed by the Corporation of Dublin, and it would appear that the arrangements for this are not yet quite complete, and the period within which it will be available for the general public is therefore uncertain. If the Corporation scheme be carried through without delay there will be much work to be done immediately. On the other hand, if no such scheme was contemplated, many business houses would be prepared to erect private installations ; but so long as this matter remains uncertain, we cannot expect intending users to lay out money on private installations which may become in part unnecessary on the establishment of a general lighting scheme. Again, the public require to be further educated as to the advantage of electric lighting. Up to the present the question which users invariably asked was simply—will my gas or my electric light bill be the heavier at the end of the year ? There are, however, I think, signs that the time is coming when in comparing the relative advantages of the systems the public will learn to place the doctors' bills, deterioration of furniture, decorations, books, &c., on the right side of the account ; and perhaps by that time we shall be getting a little tired of the oft-repeated story of the electrically frizzled horse which crops up so opportunely in the local papers whenever any electric light scheme is mooted, the scene of the cremation being laid sufficiently remote to ensure immunity from any very searching investigation. I have spoken of the deterioration of gilding, books, &c.; and perhaps I may be allowed to mention one specific case which has come under my own immediate ken. In an institution not far from where we are sitting, and in which I frequently have business, I happen to know that a sum of £50 was added to the decorator's estimates for the purpose of doing some gilding to the ceiling and cornices of one particular room. Judging by the effect already produced, though the gas is seldom used in that room, this will not last for many years, whereas if electric light were in use it would be good for fifty years. Also I understand that a considerable sum of money will have shortly to be expended in the rebinding of books, the backs of which have been completely destroyed by the products of the gas. In this particular case it would certainly have been much cheaper to use electric light than gas, even if the latter were supplied without any charge whatever. Again, electric light installations have, as every one is aware, been frequently undertaken by firms wholly without the required technical knowledge or the means of obtaining it, the result being that the work has been done in an inefficient manner, which often brings discredit not only on the particular firm which executed the order, but on the electric lighting industry in general. In our Company, as you are aware, there is no mixing up of electric light with any other business. We have in our employment an efficient staff of electrical engineers, all of whom have held positions under some of the largest and best known electric light companies now working, in addition to which, in case of any work of great magnitude, we have the advantage of the experience of

Digitized by Google

one of the oldest, largest, and most successful electric lighting companies in the world—viz., the Brush Corporation of London. Another check which has operated strongly against the rapid development of electric light is that the temptation in the case of inexperienced firms has been very strong, particularly when there is much competition, to promise too much and to cut down the estimates as closely as possible to secure the order. Your Board do not believe in the wisdom of endangering the future reputation of the Company for good, honest, and lasting work for the sake of a possibly increased show of work in the present; and while endeavouring to execute orders with as much economy as is consistent with the best results, they do not propose to undertake work (for advertising or other such purposes) which will not pay a reasonable profit. I am happy to be able to state that the estimates which we have already furnished have been drawn up on these lines. The matter of agencies in provincial towns to represent the Company has engaged the attention of your Board, and advertisements are being inserted in various papers inviting application for same. In conclusion, the Chairman pointed out the advantages to health from the use of electric light instead of gas, and stated that since the installation of electric light in the Post Office, there had been a saving of £600 a year effected, owing to the decrease of leave of absence to the members of the staff who were ill.

Mr. HASLAM proposed, and Mr. NICHOLSON seconded, the election of Sir H. Grubb, George F. Fitzgerald, Thomas J. Haslam, Emile Garcke, David Sherlock, and J. H. North, as Directors.

The motion was passed unanimously.

Mr. J. H. NORTH proposed, and Mr. WILSON seconded, the election of Sir Howard Grubb as Chairman of the Company, which was unanimously adopted.

Mr. HARRISON proposed that a sum of £200 per annum be set apart as the remuneration for the Directors other than the Managing Director, which was unanimously adopted.

Messrs. Harrison and Nichols were elected auditors to the Company.

A SHAREHOLDER asked why the contract for the lighting of the new Science and Art Museum had not been obtained by the Company.

The CHAIRMAN said the contract had been closed before the Company was incorporated.

Mr. EMILE GARCKE, secretary of the Brush Electrical Engineering Company, London, was moved to the vice-chair, and a vote of thanks was passed unanimously to Sir Howard Grubb for presiding.

Sir HOWARD GRUBB having responded, the proceedings terminated.

National Telephone Company (Limited).

Report of the Directors for the year ended April 30, 1890, to be presented to the shareholders at the tenth ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, London, on Friday, July 11, 1890, at 12 o'clock noon.

The Directors have the pleasure of submitting to the shareholders the accounts for the year ended April 30, 1890, showing a balance to the credit of net revenue account of £183,375. 19s. 7d., after providing for the amalgamation expenses and the accrued interest on the Debentures and new shares. Of this amount the sum of £66,131. 5s. has been absorbed by the payment of an interim dividend on the Preference and ordinary shares at the rate of 6 per cent. per annum for the first six months of the year. The Directors propose to pay a further dividend on both classes of shares at the rate of 6 per cent. per annum for the last half of the year, which will absorb a further sum of £66,131. 5s., and leave a balance still on hand of £51,113. 9s. 7d. In view of the near expiration of the Company's patents, the Directors think it prudent to strengthen the reserve account, and they propose, under Article 113 of the Articles of Association, to transfer to this account £40,000, leaving £11,113. 9s. 7d. to be carried forward to next year.

The extension of the Company's business during the past year has been very satisfactory, the gross annual rental from exchange, trunk, and private lines having increased from £343,544. 1s. 1d. on April 30, 1889 (prior to the amalgamation), to £392,541. 19s. 1d. on April 30, 1890, an increase in the year of £48,997. 18s.

The important trunk lines connecting London with the principal towns in the Lancashire, Yorkshire, and Midland districts, were completed as far as Edgware in January last, and the service proved to be perfectly clear and distinct. Some difficulty was then experienced in running the wires through to London, which was not overcome in time to have the connection completed before the issue of this report. The Directors have every confidence that the communication between London and the north will be established by the end of this month. A large number of additional trunk lines connecting various towns in the provinces have also been commenced during the year, many of which have been completed. These trunk lines supply a much felt public want, and will add greatly to the strength of the Company.

The Directors believe it most important to continue the policy of developing and improving the Company's system, and of giving greater facilities to the public. The capital required for this purpose the Directors propose to raise by the issue of Debenture Stock or Preference Shares, as may be found best for the interests of the Company.

The accrued rental for the year ended April 30, 1890, was £364,704. 17s. 5d., an increase of £45,162 over the accrued rentals for the National, United, and Lancashire and Cheshire Companies for the year before the amalgamation. The working expenses for the year ended April 30, 1890, amount to £148,457. 0s. 9d., being 40·7 per cent. on the accrued rental, whilst the working expenses of the three companies before the amalgamation were 47·7 per cent. This saving of 7 per cent. is owing to reductions of working expenditure rendered possible by the amalgamation.

The Directors have taken over the business of the Northern District Telephone Company (Limited), which is now merged in this Company.

The Postmaster-General not having given notice to purchase the Company's business under the power reserved by the terms of his licence, is not now entitled to do so for another period of seven years.

The auditors, Messrs. Welton, Jones, and Co., retire and are eligible for re-election.

NEW COMPANIES REGISTERED.

BAXTER'S (LIMITED).—Objects: To carry on business as general, mechanical, manufacturing, civil, marine, and electrical engineers and metal founders, and purchase or acquire businesses of such character. Capital, £20,000, in £5 shares. Registered, June 16th. Frederick U. Baxter, Director. Offices, Sandiacre, Derby.

BEALE'S (LIMITED).—This Company has been registered with a capital of £75,000, in £1 shares, to acquire the business of a public caterer, restaurateur, general provision dealer, licensed victualler, and electric light and power contractor, now carried on under the style of W. Beale and Co., at 370, 372, and 464, Holloway-road, N.

ARTHUR DASHWOOD AND SONS (LIMITED).—Registered, with a capital of £10,000 in £1 shares, to purchase the business of E. H. Dashwood, engineer, 28 and 29, St. Swithin's-lane, London, E.C., and Wimbledon, Surrey.

EDINBURGH ELECTRIC SUPPLY CORPORATION.—This Company has been formed to carry on either in Edinburgh or elsewhere the business of electric lighting, and to produce and supply electricity or electrical currents and forces, and also to provide and supply, wholly or in part, by means of electricity or electrical currents or forces, light, heat, motive

power, or forces, or telegraphic, telephonic, or other means of communication. Nominal capital £100,000, in 20,000 shares of £5 each.

HEAD, WRIGHTSON, AND CO. (LIMITED).—Objects: To take over as a going concern the business of Charles Arthur Head and Thomas Wrightson, manufacturing and civil engineers, at South Stockton, Yorkshire, and at 5, Victoria-street, Westminster, Middlesex, under the style of Head, Wrightson, and Company, adopting therefor an agreement with the said parties, the terms and conditions of which are not specified in the articles of association. Capital £210,000, in £5 shares.

INTERNATIONAL OKONITE COMPANY (LIMITED).—This Company was registered on 24th ult., with a capital of £340,000, divided into 17,000 Ordinary and 17,000 Preference shares of £10 each, together with £100,000 Six per Cent. Debentures, to adopt an agreement (unregistered) with Woodhouse and Rawson United (Limited), and to manufacture and sell insulated and other electric wires and cables for telegraphic, telephonic, and other purposes. The number of Directors is not to exceed six resident in the United Kingdom, and five in the United States of America; the first Directors in the United Kingdom are to be appointed by the subscribers; the first American Directors are F. Cazenove Jones, H. Durant Cheever, W. L. Candee, J. H. Cheever, and H. Martin; qualification for subsequent Directors, 50 shares or £500 stock; remuneration of British Directors, £1,500 per annum, divisible, and in addition 3 per cent. on all net profits other than those made by the American branch of the business; the Directors in the United States are to be called the committee of management in America, and they will be entitled to 5 per cent. of the net profits of the American branch. Solicitors, Messrs. Parker, Garrett, and Parker, St. Michael's Rectory, Cornhill.

MUNTZ'S METAL COMPANY (LIMITED).—Registered with a capital of £300,000 in £5 shares, to acquire Muntz's Metal Company (Limited) (in liquidation), and to carry on the business of manufacturers and dealers in copper, &c.

THETFORD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Objects: To carry on the business of electricians and generally to supply electric light and power at Thetford and surrounding district. Capital, £5,000 in £10 shares. Subscribers of one share each are:—G. Burrell, jun., engineer; R. G. Burrell, engineer; F. S. Burrell, engineer, all of Thetford; W. Jackson, Knottingley, Yorks.; and J. Houchen, solicitor; F. V. Houchen, solicitor; and T. Lumley, engineer, all of Thetford. First Directors (two to four) the four first above-named subscribers. Qualification, £50 in shares or stock. Remuneration to be determined in general meeting. Registered June 23rd. Registered offices, St. Nicholas-street, Thetford, Norfolk.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended June 27th amounted to £4,169, as compared with £3,156 in the corresponding period of last year.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of June were £3,300, as compared with £3,397 in the corresponding month of last year. The receipts for the month of March, estimated at £4,000, realised £4,018.

EASTERN TELEGRAPH COMPANY.—This Company announce that, subject to final audit, the accounts show, after placing about £120,000 to the reserve fund, a balance available sufficient to pay at the general meeting, on 17th July inst., the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the Preference shares, less income-tax; and a final payment of 2s. 6d. per share, with a bonus of 3s. per share, both free of income-tax, on the Ordinary shares, making, with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ended March 31, 1890. The transfer books of the Company will be closed from the 10th to 17th July, both days inclusive.—The traffic receipts of this Company for the month of June amounted to £51,019, as against £44,805 for the corresponding period of 1889, or an increase of £6,214.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—Coupon No. 2 on the Debentures of this Company is now payable by Messrs. Dimsdale and Co., 50, Cornhill, E.C.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—An interim dividend for the quarter ended March 31st last of 2s. 6d. per share has been declared by the Board, payable on the 15th inst.—The traffic receipts of this Company for the month of June amounted to £43,198, as against £39,350 for the corresponding period of 1889, showing an increase of £3,848.—This Company notifies that the coupon on the Five per Cent. Australian Government Subsidy Debentures, due on July 1, will be paid on and after that date, by Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C.

INTERNATIONAL OKONITE COMPANY (LIMITED).—The prospectus of this Company was issued early this week, and announces that the Company is formed to undertake the manufacture of insulated telegraph, telephone, and other electric wires and cables. The share capital is £340,000, in 17,000 Preference shares and 17,000 ordinary shares of £10 each, in addition to 1,000 Six per Cent. Debentures of £100 each, equal to another £100,000. These debentures are a first charge on the entire undertaking, and are to be redeemed on July 1, 1910, at par, and a dividend of 8 per cent. is to be paid on the Preference shares. The consulting engineers to the Company are Sir William Thomson and Dr. John Hopkinson. In addition to taking over the large business done in America by the Okonite Company, this Company also absorbs that of Messrs. Shaw and Connolly. We must refer our readers to the prospectus for an account of the business now being done by these firms, and for particulars of the somewhat roseate outlook for the future anticipated by the promoters. The list of applications was opened on Tuesday last and closed on Wednesday. Messrs. Woodhouse and Rawson are the promoters of the venture, and must have great confidence in the undertaking to leave the subscription lists open for so short a time.

MAXIM-WESTON ELECTRIC COMPANY (LIMITED).—A meeting of this Company was held on Wednesday last at Winchester House, Old Broad-street, "to discuss the position of the Company." The meeting was private, and our representative was refused admittance. We understand, however, that the shareholders are to be asked to subscribe a further sum of £3,000 to enable the Directors to carry on the business of the Company. The Chairman (Mr. Blades Gooding) expressed his belief that there was a very fair prospect of their Company being able to do a profitable trade in view of the present extended use of the electric light, and of the inevitable demand for the light on an economical scale. A discussion followed, generally of a favourable character, and several of the shareholders present offered to subscribe further money. It was suggested that an appeal should be made to the shareholders, and an issue of debentures on a small scale was recommended.

OBITUARY.—The death occurred on Sunday last of Mr. Francis Bennoch, a gentleman who was well known in City circles, and was one of the Directors of the Venezula Telephone and Electrical Appliance Company.

STOCK EXCHANGE.—Application has been made to the Committee to allow the Commercial Cable Company $7,216,000 capital stock to be quoted in the official list.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month ended June 30, 1890, amounted to £5,475.

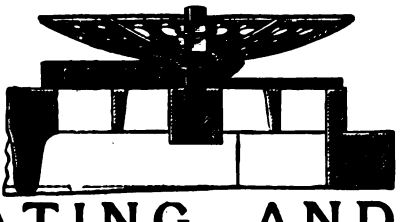
WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this Company for the half-month ended June 30th show an increase of £353 as compared with the corresponding period of last year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended June 27, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,216, as compared with £2,017 in the corresponding period of last year.

WESTERN COUNTIES TELEPHONE COMPANY (LIMITED).—An extraordinary general meeting of this Company was held at the offices, High-street, Bristol, on Friday last, when the resolution, passed at the extraordinary general meeting held on May 30th last, was confirmed as a special resolution. It effects several alterations in the Articles of Association rendered necessary by the amalgamation of the National and United Telephone Companies, and substitutes the name of the former for that of the latter throughout.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 634.—Vol. XXV. FRIDAY, JULY 11, 1890. Price Fourpence.

NOTES.

From the answers given in the House of Commons by Mr. Raikes, and in the House of Lords by the Earl of Jersey, with regard to the Government's decision not to purchase the telephone companies' interests, we may reasonably infer that, instead of buying up the business outright, the Post Office authorities rely upon its falling into their hands sooner or later on their own terms, or by process of natural selection. Competition is talked of when the patents expire next year; and it would seem that the chief competitor will be the Post Office itself. This is a rather serious outlook for the patentees, especially as they have not been able, or, perhaps, not particularly anxious, to win over public sympathy on behalf of their exclusive monopoly. The principal company may have some ground of complaint against the Government; but, so far as the public are concerned, we believe they will contemplate with profound indifference any action that may be taken to put the telephone administration—at all events, that of the metropolis—into different hands. What the Directors may think of the prospect now before them will probably be made known at the National Telephone Company's meeting on Friday; and we must reserve further comment until next week.

There are hardly enough data in the account of Dr. Paul Schoop's gelatinous accumulator, which we publish to-day, to enable a fair comparison to be made between this ingenious invention and an ordinary secondary battery with dilute sulphuric acid. One would expect to find a high resistance, and a sluggish action, due to the necessity for diffusion. The increased resistance is admitted, but is stated to be unimportant. It must, however, be remembered that, small as the resistance of an accumulator is compared with the older forms of primary batteries, it already presents very considerable drawbacks, and places the use of storage batteries at a great disadvantage where heavy discharges are demanded. A jelly would be more desirable than an acid solution under the seats or floor of a tramcar, but already a limit has been reached in this application of electricity, which is due chiefly to internal resistance. If an attempt be made to discharge an accumulator in less than four hours, there is a serious drop in volts; and, even if the plates are not damaged, there are heating and several other evils. One of the best batteries for standing a heavy discharge has a very wide space between the plates, which of course decreases the conductivity. Dr. Paul Schoop says that when his gelatinous acid is used, the distance between the plates may be reduced, thus bringing the resistance down to an ordinary amount. If he can go farther and *actually* reduce it, he will do well. Tramcars do not need a four or five hours' supply. In many instances it would be far better if a supply for only two hours could be carried, provided that the weight of the batteries might thus be halved. The electrical omnibus would have a fair chance if a battery could be found which would do the bulk of its work in an hour and a half. A low resistance is not all that is wanted; but with a low resistance and a gelatinized solution, great strides might be made in electric traction by accumulators.

From Mr. Carter's reply to our comments on the magnetic circuit last week it appears that he has quite misunderstood their purport. We had no intention of implying that his analogy was in any way incorrect. We, however, wished to point out that, by comparing magnetic flux with electric charge instead of with electric current, the analogy can be pushed much further than it is otherwise possible to do. Mr. Carter's analogy is, indeed, a good one; but it cannot be much extended without breaking down. No doubt, magnetic induction, like the electric current, is of the nature of a flux; and each has a rate of fall of potential; but this is also true of electric charge, and, this being the case, we may compare the former with either of the latter. Clearly, the better one to choose is that which will yield the most complete analogy; and a little consideration will show that the electrostatic analogue is in this sense the right one to take.

With the electric circuit the product of the current by the fall of potential gives the rate at which energy is being expended, either in heating the circuit or for other purposes, while with the magnetic circuit the product of the number of lines by the fall of potential is a measure of the magnetic energy *stored*. This energy shows itself in the extra currents induced, when from any cause the magnetism is altered, and is quite analogous to the store of energy possessed by a condenser, and measured in precisely the same manner by the product of the charge and the potential of the coatings. The main objection which Lord Rayleigh, Dr. Hopkinson, and others have urged against the adoption of the term "magnetic resistance" arises from the association of the word "resistance" with "continuous expenditure of energy," and that, in conse-

Digitized by Google

quence, such an extension of its use would be misleading. For similar considerations, Mr. HEAVISIDE proposed that the word "reluctance" should be substituted for "resistance," since the quantity denoted is analogous with the constant of a condenser, and not with the resistance of a wire. An electromotive force may charge a condenser by displacing a quantity of electricity proportional to its capacity, or generate a current in a wire by producing a continuous displacement of electricity, at a rate inversely proportional to the resistance. In the same way, a magneto-motive force may produce a number of lines of induction proportional to the electro-magnetic capacity of the circuit; and if a true magnetic conductor were known it would generate a magnetic current by producing a continuous displacement of lines.

THERE is one point in Mr. CARTER'S letter to which we must take exception. If the electrostatic analogy fails at some points, it certainly does not do so in the instance put forward. Mr. CARTER says, "The number of lines of *force* radiated from unit magnetic pole is independent of the medium, *i.e.*, the *stress* is independent." If by the word *force* Mr. CARTER means *induction*, the former part of the statement is right; but whether this is meant or not the latter part is incorrect. Mr. CARTER has, in fact, from disapproving the analogy between electric and magnetic charges, confused lines of induction with force in one case, and very clearly pointed out the distinction in the other.

THERE are some good points about the Smythe and Payne cut-out, which is described in another column, as it would appear that the size of the attachment cord is not of any great importance. The device seems to be open to the objection that its action would not be always instantaneous. If the cord be rather too thick, it will take an appreciable time to burn through; and the mechanical movement of the parts will also occupy a measurable interval. This objection was raised by a contemporary, some years ago, to a magnetic cut-out where a magnet released a tumbling weight or hammer by which a switch was knocked over; the objection, we think, is not unimportant. Have any experiments ever been made to ascertain if a sudden heavy current has time to do any damage before an ordinary cut-out has time to melt?

ONE or two fires have occurred in this country which must be attributed to the electric light. It is possible that in more than one case the real cause may be known either to the contractor who wired the house, or to an inspector who has subsequently examined it. In the absence of inquests as to the causes of fires, the true circumstances will rarely be made public. It is surmised that wood-casing set in damp plaster and never becoming properly dry; or casing which has subsequently become damp, may have set up some electrolytic action, resulting in a leak, then in charring, and eventually in a fire. The insulated cable used in the highest quality of wiring would oe safe for years in water. Can damp wood or damp plaster damage sound cable? Probably not. But if there be a leak, sufficient to allow, say, one hundredth of an ampere to pass from wire to wire, or from wire to earth, will damp wood and damp plaster tend to increase this leak? Many engineers say yes. Then, what will take place? The leak may be between two mains carrying 20 amperes, with a 24 ampere fuse. Can 24 amperes get across a reasonable distance through damp wood—if so, with what effect? Would a smaller current, which would not melt the fuse, do any damage? Is it a matter of time? Can a trifling leak develope into a dangerous short-circuit, under the conditions to which we have referred, in an hour, a week, a year? Does the current finally increase at a rapid rate? Can any one answer these questions from actual observation? If not, we hope that some experiments will be made. Nothing could be more easy, say, at a central station or laboratory than to put up a length of jerry work, including a bad joint or two; keep it damp, keep the current on, and keep a careful watch upon it; and, finally, send a report to our columns.

IN our issue of the 6th June we published a brief description, abstracted from a Belgian technical magazine, of the electrical arrangements on board the "Peral" submarine torpedo boat. Lieutenant Peral, as we announced a few days ago, has for his invention been awarded the sum of £20,000 by a grateful country; but we have it on the authority of the Paris *Figaro* that "the satisfaction of M. Peral has been troubled by an incident which is not without gravity. An English review, *The Electrician*, has published a complete description of the depth-regulating apparatus of the 'Peral;' and the question is, who can have betrayed this secret to the English. The matter is somewhat delicate, and it is to be hoped that an inquiry will be instituted. At Cadiz this publication has produced a profound impression, and M. Peral does not dissemble his vexation."

WE learn by telegram, just as we are going to press, that the Town Council of Brighton have accepted the tenders which we give in another column.

Drogheda.—The Irish House-to-House Electricity Company have announced their intention of applying for a Provisional Order.

Blyth.—The Local Board has received notice that it is the intention of a company to seek powers to supply electricity within its district.

Chesterfield.—The Corporation has received notice from Messrs. Cowdell and Davies of the intention of a syndicate to apply for powers to supply Chesterfield with electricity.

Acton.—A communication has been received by the Local Board from the House-to-House Electric Lighting Company to the effect that they intend to apply for a Provisional Order.

The Meudon Balloon Experiments.—According to *La Lumière Electrique*, the Meudon dirigible balloon is worked with a 70 horse-power electric motor, weighing only 490 kilogrammes.

Colchester.—At the last meeting of the Town Council a letter was read from Messrs. Latimer, Clark, Muirhead, and Co., stating that they intend to apply for a Provisional Order.

Electric Traction in Rome.—The tram line erected by the Series and General Electric Traction Company in Rome on the Series system was opened by the King of Italy on Sund y last.

Digitized by Google

Worthing.—At the last meeting of the Local Board a letter was read from the Laing, Wharton, and Down Construction Syndicate, announcing their intention of applying for a Provisional Order.

Tunbridge Wells.—At the last meeting of the Town Council it was stated that the Electric Light Committee had agreed to ask the Council to make application for powers to light Tunbridge Wells by electricity.

Alnwick.—A communication has been received by the Local Board from the Northern Counties Electric Lighting and Power Supply Company, informing the Board that it is the Company's intention to apply for a Provisional Order.

Hamburg.—The Bremer electric tram, constructed by the International Thomson-Houston Company, at Hamburg, was opened on July 1st, and carried on the first day, with the three cars at present in service, 2,500 passengers.

Telephonic Extensions.—A telephone trunk line was opened last week, connecting Weston-super-Mare and Bristol.—The trunk wire between Dundee and Aberdeen *vid* Falkirk, Brechin, and Montrose, a distance of 200 miles, has been completed.

Southport.—The Corporation have received two notices of intended applications for Provisional Orders to supply electricity within the borough; and the Gas Committee have decided to recommend the Town Council to refuse their consent, and to apply themselves for an Order.

Electrical Bills in Parliament.—The Drypool Gas (Electric Lighting) Bill was read a third time in the House of Commons on Thursday evening. The Royal Assent was given on Friday last to the Electric Lighting Acts Amendment Bill (Scotland), and to the North Metropolitan Tramways Bill.

Electrical Units.—We are asked by Mr. R. T. Glazebrook to announce that it is expected that a discussion will take place at the forthcoming meeting of the British Association in connection with the Electrical Standards Committee on the best values to adopt for the units of electrical measurement.

Halifax.—At the last meeting of the Town Council, the Town Clerk read a letter from the National Electric Supply Company, giving notice of their intention to apply for a Provisional Order. The Town Clerk said a similar notice had been received from the Yorkshire House-to-House Electricity Company.

Loughborough.—At the last meeting of the Town Council notice was received from the Loughborough Electricity Supply Company of their intention to apply for a Provisional Order. This was accompanied with a letter stating that the application was made on behalf of the Brush Electrical Engineering Company.

Electrical Trades Section River Excursion.—The inclement weather on Saturday reduced the number of the party from 50 to 21. Owing to a hitch in getting ready the electric launch, the trip was made by steam. When the accounts are made up the balance will be returned to those who took tickets but did not go.

Troyes.—A workman connected with the recently-inaugurated transformer station at Troyes, who had been engaged in connecting a transformer to the mains, stumbled on leaving the cellar in which he had been at work, and fell. In his fall he caught hold of the transformer and pulled it completely down, and received a fatal shock.

London Chamber of Commerce.—The following gentlemen were amongst those elected members of the London Chamber of Commerce at the last Council meeting:—J. A. Brown, electrical engineer; W. Johnson, secretary and engineer of the Sheffield Telephone Exchange and Electric Light Company; Arthur Shippey, electrical engineer.

City and Guilds of London Institute.—The post of Senior Demonstrator and Lecturer in the Department of Electrical Engineering at the Technical College, Finsbury, has become vacant by the appointment of Mr. Robinson to the Professorship of Mechanical Engineering at Nottingham. Further particulars will be found in our advertisement columns.

The Post Office Jubilee Conversazione.—We are glad to hear that the net result of this *Conversazione* has been an addition of £10,000 to the Rowland Hill Benevolent Fund. It is to be hoped that this result, of which the Post Office may well be proud, will still further mitigate whatever mild indignation may have been caused by the "electro-phonoscope" hoax.

The Telegraph in South Africa.—The first office in the British South Africa Company's telegraph system has been opened at Ramoutsa, in the British Protectorate, 77 miles north of Mafeking. The second, at Mascheedi, about 50 miles further north, will be ready next week. Cablegrams for these offices will cost 3d. per word in excess of the present tariff.

Exeter.—The Town Council having been applied to by the Devon and Cornwall Electric Light Supply Company for sanction to apply for a Provisional Order to light the city with electricity, it was resolved at the meeting on Wednesday to appoint a committee to consider whether the Corporation should not itself apply for a Provisional Order for the same purpose.

Electric Launches.—We are informed by Woodhouse and Rawson, United, that they have purchased the business of electric and steam launch builders formerly carried on by Messrs. W. Sargeant and Co. at Strand Works, Chiswick, W. Mr. Sargeant has been retained as branch manager; and they intend to pay special attention to the building of electric launches and charging stations.

Copper.—Even with the advance in prices, the demand for copper, says *The Statist*, appears to be expanding, and for June the deliveries are reported as amounting to the very large total of 18,781 tons, the largest monthly delivery on record. The supplies of the month have been a little (400 tons) larger than in the previous month, and the stock has been reduced by nearly 10,000 tons, amounting on June 30th to 72,493 tons, against 111,689 tons this time last year.

Submarine Cable Manufacture in France.—The submarine cable between Demerara and Cayenne, a distance of 230 miles, has just been laid. This is the first submarine cable constructed by the Société Générale des Téléphones since it took up this branch of cable manufacture. The same firm have in hand 3,000 miles of cable for the Société Française des Antilles. The Société Générale is erecting large submarine cable works at Calais, and has given an order for the construction of a cable ship.

Bath.—At the last meeting of the Town Council some letters by the Bath Sanitary Committee were read, calling attention to defects in the electric lighting which had disclosed themselves since the wet weather set in. Mr. Massingham, it seems, has expressed his regret for the imperfections, and pointed out that they arose from the fact that the wet weather had found out weak connections between the mains and the lamps, which owing to the work being hurried towards the last had not been found out by experimental runs.

University College of South Wales.—Dr. Elliott, of the University of Edinburgh, out of a total of 39 candidates, has been appointed Professor of Engineering at the University College of South Wales and Monmouthshire. He will enter upon the work of the organisation of his department, planning out the necessary buildings, &c., at once. Dr. Turpin, who is a graduate of the University of London, and a first-class man in the Natural Science Tripos at Cambridge, has been appointed Lecturer and Demonstrator in Chemistry at the same College.

Amsterdam.—The Town Council has passed the Bill fixing the rules and conditions under which the electric lighting of Amsterdam shall be entrusted to those tendering in open competition for the contracts prior to September. The contractors will have to pay the Corporation 5 per cent. per annum on all receipts; of the balance, 6 per cent. will go to the contractors, who will also receive one moiety of the surplus, the other moiety going to the consumers. The Town Council is to have the right to readjust the charges for electric lighting every five years, and may lower them if found unreasonable or excessive.

Wire Table.—An "International Wire Table," compiled by Mr. Wilfred S. Boult, will shortly be published, containing full particulars of 451 electrical conductors, ranging from 2·26in. to ·001in. in diameter, and including single wires and cables of

Digitized by Google

the Standard, the Birmingham, the Brown and Sharpe, and the metric gauges, arranged in consecutive order according to cross-section, so that when any conductor is looked up it is at once seen what are the nearest sizes in the other gauges. Full particulars will be given with regard to each of the 451 conductors as to cross-section, gauge, weight, and resistance, in English, American, and Continental units.

Electricity and the Law.—In a recent number of the *Political World* it is pointed out that nobody knows under the Electric Lighting Acts whether central-station plant, on being purchased by a Local Authority, is to be valued as an integral part of a working and successful concern—if the concern be successful—or simply as so much isolated machinery and material distributed in different places. "That," remarks the *Political World*, "is the pleasant little problem which our disinterested lawyers—always ready to help the nation in its difficulties—are looking forward to solve in the future. In the meantime, might not our legislators bring in a few interpreting Acts?"

Leeds.—The following additional particulars with regard to the electric light installation at the offices of the *Yorkshire Post*, to which we referred in our last issue, may be of interest. The order for the installation was only given to Mr. Wilson Hartnell at 11 o'clock in the morning, and it was at work at a few minutes to 11 the same night. Operations were commenced at 2 p.m. The power for driving the dynamo was already on the premises, but excavations had to be made to make room for the driving pulley on the main shaft. Pulleys had to be bored and turned, a special countershaft had to be provided with the necessary pulleys, foundations for dynamos, &c. At five minutes to 11 the work was so far completed that the whole of the composing-rooms, where over 100 hands are employed, the printing machine room, and, in fact, the whole place where night work is required, was brilliantly illuminated.

The Manufacture of Celluloid.—The manner in which celluloid is made in France is as follows:—A huge roll of paper is unwound slowly, and while unwinding is saturated with a mixture of five parts of sulphuric and two parts of nitric acid, which is carefully sprayed upon the paper. The effect of this bath is to change the cellulose in the paper into pyroxyline. The next process is the expelling of the excess of acid in the paper by pressure and its washing with plenty of water. It is then reduced to a pulp and bleached, after which it is strained, and then mixed with from 20 to 40 per cent. of its weight in water. Then follows another mixing and grinding, after which the pulp is spread in thin sheets, which are put under enormous hydraulic pressure and squeezed until it is as dry as tinder. These sheets are then put between heated rollers and come out in quite elastic strips, which are worked up into the various forms in which celluloid is made.

Thunderstorms.—Further accounts show that the thunderstorms which occurred at the end of last week did considerable damage both to life and property. At Chapel St. Leonard's, near Sutton-on-Sea, a waggoner was working with a reaping machine when he and his horse were struck by lightning and killed. At Hanslope (North Bucks), some barns were struck by lightning and caught fire. The buildings were entirely consumed. At Ilmington, an oak tree was struck and the lightning took the top of the tree completely off, leaving the body of the tree, which was about 10ft. high, split down to the ground, the bark being projected a distance of thirty yards. In the Cleveland district, the Eston Steelworks were struck by lightning, and a portion of the roof collapsed, bringing to the ground five principals and a girder, several tons in weight. At the time of the occurrence a large number of men were engaged in this portion of the works, and four were injured by the falling material.

Gas Pipes damaged by Lightning.—On the 28th ult., during a severe storm, Filey Church was struck by lightning. The church tower is surmounted by a weather-cock attached to an iron rod fixed on an oak mast. The lightning struck this mast just where it was joined to the rod bearing the vane, and, splintering it into matchwood, tore up the lead covering of the roof, and running down the side of the building smashed a pipe connected with the heating apparatus. It seems then to have entered the church, but without doing any damage until it reached the ground, where it snapped upwards of 12 gas-pipes connected with the main outside. Running underground along this main, the electricity broke the main-pipe in several places at the junctions, until it reached a point opposite a farm-house, where it extinguished the gas in a cooking-range, and went apparently to earth. The gas-main is a 1½in. cast-iron pipe with turned and bored joints. The damage extended over some 80 yards; and, in that length, eight or nine of the sockets were split open, in some instances pieces of the sockets being broken completely off. The fractures were all on the underneath side of the pipes. The soil is a clayey loam, and was fairly dry. The church had no lightning conductor to it.

The Series Storage Battery.—Messrs. Mark Bailey and Co., of Cadby Works, Leather-lane, have submitted to us a specimen of their new storage batteries. These are intended, at present, for use on a small scale, for carriage lighting, &c. The battery consists of a wooden cell, divided into separate partitions by the battery plates. The opposite sides of a plate are therefore of an opposite character; one side being as it were, positive, and the other negative. The plates in a cell are therefore in series, and no electrical connections whatever are required, except at the two end plates. A wooden frame between the plates prevents buckling. A box 14in. long, 4½in. wide, and 6in. deep, will contain a battery of 24 plates, that is 24 cells; and this, we are informed, will yield 18 amperes at 48 volts. The plates are cast with square recesses, for holding the peroxide, and probably would discharge at a rate comparing fairly with other accumulators. For lightness and small space the arrangement appears very good; but in the absence of any prolonged test for durability, it is impossible to say whether the tendency to buckle has been overcome. Some six years ago we tried the series arrangement of conical cells, which has been re-invented scores of times; buckling does not describe the contortions into which the soft lead plates threw themselves.

Eastern Telegraph Company.—The Report of the Directors of this Company for the half-year ended March 31st last will be found in our present issue. The Directors announce the conclusion of arrangements with the French Government for the renewal of the agreement for the Company's direct line through France, and for the landing and working of submarine cables at Marseilles; and also the renewal of the agreement between the Postmaster-General and the Company for a special wire by land line and cable connecting the French line with London. The Italian Government have prolonged for twenty years the existing concession to the Company for the working and maintenance of their cables between Italy, Malta, Corfu and Egypt. The Company have also concluded an agreement with the Turkish Government for a short cable between the island of Perim and Sheikh Seyd, by which the Company's system will collect traffic from various points on the Arabian coast. The Directors state that the Company's interests were carefully watched at the recent International Telegraph Conference at Paris by the Chairman, the Managing Director, and other representatives of the Company, and that the result has been on the whole not unsatisfactory. The Report concludes with the announcement that the new Red Sea cable, to take the place of the original cable connecting Suakim with Suez and the Island of Perim, will most probably be in working order before the end of the year.

Investigation of the Stanley Alternate-Current Arc Dynamo.—The graduating thesis of Messrs. Tobey and Walbridge, of Cornell University, embodies an experimental investigation of the new Stanley alternate-current arc machine. The general method was to obtain instantaneous values of electromotive force and current at a sufficient number of points to indicate by curves the performance of the machine at every part of a revolution. For this purpose a condenser was charged by a suitable commutating device to the potential it was desired to measure, and then discharged through a ballistic galvanometer. Readings of arc and field current were taken by fall of potential method. The E.M.F. curve exhibited a very peculiar form, approximating more nearly to a rectangle than to a sine curve. The reversal of

Digitized by Google

direction was very abrupt, the E.M.F. at a load of 20 lamps changing during 3·8deg. from 960 volts positive to 1,560 negative, making a total of 2,520 volts. This effect is due to the action of the arc, for when the machine worked on non-inductive resistance (incandescent lamps), the curve of E.M.F. approximated quite closely to a sine curve. The arc current in all cases approximated to a sine curve, and the field-current exhibited a wiry form, the maxima of this and the arc current curves corresponding. The current lag in all cases was very small, increasing slightly as the load increased. The zeros of both E.M.F. and current moved backward slowly with reference to the pole-pieces as the load became greater. For all runs yet taken for over half load, the machine showed an efficiency of over 90 per cent.

Cape Telegraphs.—The following notes are extracted from the report of the Postmaster-General of the Cape of Good Hope:—The postal and telegraph business having grown amazingly since 1872, when the present offices were taken, a building specially designed for the service has become necessary, and during the last Session the sum of £10,000 was voted to acquire a site. During the year 2,824,153 messages, containing 58,499,902 words, were received and forwarded. There were 4,510 miles of telegraph, carrying 11,325 miles of wire, and necessitating the use of 411 sets of apparatus. The telegraph receipts for the year were £94,929, as compared with £70,243 in the previous twelve months, the value of Government messages being £47,490. The total revenue, reckoning Government telegrams, was, therefore, £142,419, and the expenditure on working and maintenance £67,232, leaving a profit on working of £75,187, equal to more than 19 per cent. on the total capital expended on telegraph lines to December 31st, 1889, which was £387,448. The question of free transmission of newspapers throughout the Colony has been mooted, but the Postmaster-General has not felt himself at liberty to favour the proposal. The experiment has been tried by only two or three out of all the postal administrations in the world, amongst which are Natal and New South Wales. The Postmaster-General of both these colonies report against the free carriage of newspapers, on the ground that the postal service was carried on at a loss. The estimated loss to the Cape Colony owing to the exemption of newspapers from postal charges would be about £12,000 per annum.

The Birkenhead Electric Lighting Bill.—This Bill came before a Select Committee of the House of Commons, presided over by Mr. Stansfeld, on Thursday last week. The National Telephone Company were the only opponents. The point on which there was opposition was contained in the sixth clause, which provided that the undertakers should so construct their works that they should not injuriously affect the working of any existing telephonic or telegraphic circuits. The opponents desired that the word "existing" should be left out of the clause, so that it should apply to works that might hereafter be constructed. Dr. Fleming and Mr. Shoolbred, C.E., gave evidence on behalf of the promoters, and Sir William Thomson and Dr. John Hopkinson gave evidence on behalf of the petitioners. It was announced that this being a test case, whatever the Committee decided would be adopted by the Board of Trade, and amendments made accordingly in all the Orders now before Parliament. The clause as amended runs as follows:—"The undertakers shall construct their mains and other works of all descriptions, and shall work their undertakings in all respects, so as not injuriously to affect the working of any existing electric circuits from time to time used, or intended to be used, for the purpose of telegraphic, telephonic, or electric signalling communication, or the currents in such circuits, and shall use every reasonable means in the construction of their mains and other works of all descriptions in the working of their undertaking to prevent injurious affection, whether by induction or otherwise, to any electric circuits used or intended to be used for the purpose aforesaid, whether existing at the time of the construction of such mains or other works or not."

The Modling-Hinterland Electric Railway.—In a recent number of the *Révue Générale des Chemins de Fer*, M. Maurice Bellom gives some particulars with regard to this line, the first section of which was in operation as far back as 1883, and the last section of which was completed in 1885. The line is of 1 metre gauge and 4·4 kilometres (2¾ miles) long. The steepest gradients are 1½ per cent., and there are some curves of 100 feet radius. The plant comprises one 140 and three 15 horse-power engines, and six compound-wound Siemens machines, having an output of 30 amperes at 500 volts. The motors, which are series-wound Siemens machines, are arranged under the car, spur gearing being used, and the speed being reduced in the ratio of 6 to 1, the cars running as a rule at the rate of 9½ miles per hour. The circuit is entirely metallic, and runs overhead on wooden posts 18ft. high and 90ft. apart. The conductor consists of a split iron tube, in which there slides a brass contact piece attached by wires to the roof of the car. To take the strain off the conducting wires, the slot is pulled along by means of a rope. The overhead arrangements are, in fact, similar to those employed in the Frankfort-Offenbach line, described in *The Electrician* of March 23, 1888. The contact piece lasts for about two months without renewal. During the winter only one train is employed, but during the busy season three trains, and on Sundays and fête days six trains are running simultaneously. Each train consists of a thirty-passenger motor car, weighing 4·1 tons, and a thirty passenger car without a motor, weighing 2·8 tons. These weights, together with a full complement of passengers, make a total load of 11·1 tons. The maximum resistance to traction is found to be about 24lb. per ton. With six trains running, 8,000 passengers can be carried in a working day of 14 hours. Tests have shown that with a single train at work, the difference of potential at the dynamo terminals is 500 volts, and at the distant terminals of the line 390 volts, the current strength being 30 amperes. The first cost of the line was somewhat high, amounting to a grand total of 1,317,714fr. (£52,708). The working expenses in 1887 were 36,645fr. (£1,457), leaving a net profit of 67,539fr. (£2,701). In 1888 the net profits were 71,089fr. (£2,850), or 5·4 per cent. upon the first outlay.

A Time Circuit Cut-Out.—One of the troubles incurred in commercial lighting, says the *Electrical World*, is that part of the customers require lights, say up to 7 o'clock p.m., another portion till 9 or 10 o'clock, and still others until midnight; and these various patrons are not considerate enough to arrange themselves so that a separate circuit can be conveniently supplied to each class. An appliance has been brought out by a Mr. Elkins, of Boston, to give the central station absolute control over all the lamps supplied by it, and to enable all lamps belonging to one class of service to be shut off at the proper hour. The apparatus consists of a step-by-step ratchet movement, actuated by a small electro magnet and controlling spring switch, which short-circuits the loop containing the lamps which it is intended to cut out. A small pin inserted at various points in a dial above the ratchet wheel adjusts the apparatus to spring the switch by any desired number of movements of the magnet. The working of the circuit is as follows:—A special circuit is used, and in it all the cut-outs are inserted in series to each other. At the station this circuit is cut into the main line across the terminals of a resistance through which the current can be shunted. The difference of potential between the ends of this resistance is sufficient to throw the desired current around the signal circuit. Let it be supposed that it is desired to run on the same line 7 o'clock lights, 9 o'clock lights, and midnight lights. At the entrance to each customer's place of business is placed the cut-out in a closed box. The ratchets of all cut-outs to control 7 o'clock lamps would be adjusted to spring the switch by three impulses of the magnet; all the 9 o'clock lamps would be adjusted to require, say, five impulses, and the midnight lamps seven. At 7 o'clock the operator at the central station would open the switch in the loop containing the resistance, and would then press the key in the signal circuit three times, which would cut out all the 7 o'clock lights on the line. At 9 o'clock two additional strokes of the key would cut out the 9 o'clock contingent, and at midnight two more strokes would extinguish everything except the all-night lights. When the lamps are trimmed in the morning the trimmer inserts the key in the box and sets the cut-out ready to be operated at the desired hour.

MAGNETISM IN IRON AND OTHER METALS.*—XXIII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 223.*)

§ 89. **Further Experiments on Time-Lag in Magnetisation.**—Similar differences between the immediate and ultimate action of magnetic force on soft iron present themselves when we examine the effects of small increments of the magnetic force at any stage in the process of magnetisation. In another experiment, which was made with the same specimen of annealed wrought iron, the magnetising force was applied in a series of small steps—each step being produced by a rapid but not quite sudden augmentation of the magnetising current. The immediate effect of each step was balanced by means of the compensating coil, and after each step a pause of one minute was made during which the gradual growth of magnetism was observed. The results are shown in the full lines of Fig. 60; the dotted line has been added to show that the points reached after the pauses of one minute lie in a continuous curve. As the experiment was continued into higher points of the magnetisation curve, the compensating coil had to be pushed a little nearer the magneto-meter to procure a perfect balance: in other words, the immediate effect of the step became somewhat greater. At the beginning, the instantaneous value of $\frac{dI}{dH}$ was about 10; but when the experiment of Fig. 60 was extended until the force produced by the magnetising solenoid was 3 C.-G.-S. or, so and I was about 320, the instantaneous value of $\frac{dI}{dH}$ rose to 13. At that region of the curve, the creeping-up of magnetism after a very small step-up of the current was enormous; in the course of one minute it amounted six or seven times the immediate effect of the step. Fig. 61 illustrates the kind of action which is observed when a small increment of magnetising force is made to take place quickly after a pause anywhere in the steep part of the magnetising process, the metal dealt with being soft wrought iron. The dotted line is the normal slope of the magnetisation curve when the process of magnetising is performed slowly. A very small increment of H rapidly performed after a pause at P produces an immediate effect, P Q, which is followed by the slow creeping up Q R. It is only when the step is a very small one that P Q correctly represents the immediate effect.

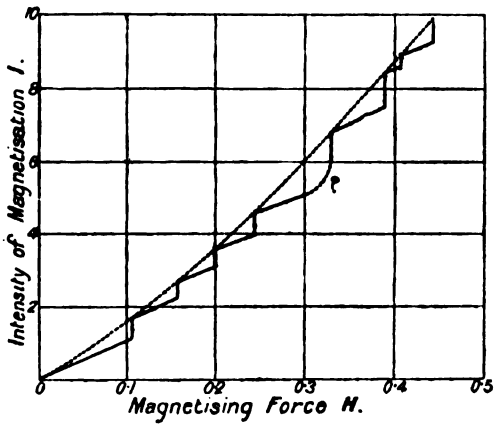

FIG. 60.—Effects of steps in the magnetisation of a soft iron rod.

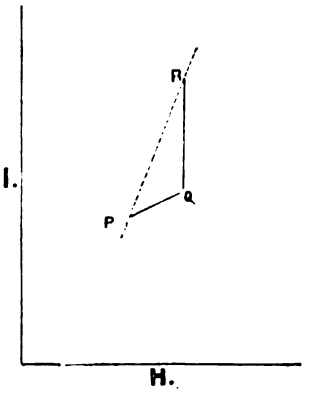

FIG. 61.

Very interesting results are obtained in examining how the time rate of creeping up after a step is affected by the length of the pause (under constant force) which preceded the step. When the preceding pause is long the creeping up which follows a step goes on much more slowly than when the preceding pause is short.* In an experiment with the same specimen of soft iron the effects of two equal small steps were compared, both made in the same region of the magnetisation curve, one after the magnetising force had been kept constant for three minutes, and the other after it had been kept constant for an hour. The immediate effects were the same; but the subsequent creeping up, which was observed during no less than ten minutes, went on so much faster in the former case that it amounted in ten minutes to 531 scale divisions of the magnetometer, as against 320 scale divisions in the latter.

The effects of an alternate small step up and step down, performed at any stage in the process of magnetisation, are quite like those that have been shown in Fig. 57. After the steps have been repeated often enough to bring about a cyclic set of changes, the instantaneous value of $\frac{dI}{dH}$ becomes approximately the same as at the initial part of the curve—namely, about 10 in the particular specimen examined—unless the whole magnetisation approaches saturation, in which case the value of $\frac{dI}{dH}$ is distinctly less. The diagram (Fig. 62) represents in a general way the change of magnetism which takes place when any very small periodic variation of magnetic condition is made to occur in a soft iron bar, about a mean condition O. If the changes of force occur fast and without pauses the cycle is shown by the lines $a\,a'$ and $a'\,a$. They enclose no area, and there is no dissipation of energy. If, on the other hand, the changes of force occur gradually and very slowly the cycle is shown by the lines $c\,c'$ and $c'\,c$. They also enclose no area; and again there is no dissipation of energy. But if the changes of force take place quickly, with pauses at the extreme values, the cycle is $b'\,c'\,b\,c$, and an amount of energy is dissipated which is to be measured by the area of that parallelogram. In most actual cases in which the force varies periodically it does so not suddenly with pauses at the extreme values, but in such a manner that a loop will be formed instead of the parallelogram. When the frequency of the alternations is very great, the loop will flatten itself into the straight line $a\,a'$; when the frequency is very small it will again flatten itself into the straight line $b\,b'$. With any frequency lying between these extremes there will be dissipation of energy, and when the limits and mode of variation of the force are specified, there must be some particular frequency which will make the amount of energy dissipated in the cycle a maximum.

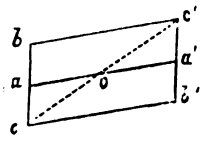

FIG. 62.

In hard iron and in steel the phenomenon of time-lag in magnetisation occurs, but so slightly as to be scarcely observable. A piece of the same wire as had been used in the above experiments was hardened, after being annealed, by stretching it a little beyond the limit of elasticity. Scarcely a trace of creeping could be detected when a feeble magnetic force was applied

* All rights are reserved.

* *Loc. cit.*, p. 280.

Digitized by Google

to the wire in this hardened state, but it was possible to produce a measurable amount of creeping by first applying a moderately strong magnetising force, and then making a small step up after a pause. The initial instantaneous value of $\frac{d\,I}{d\,H}$ for a small step was 5·3.

The whole phenomenon depends much on the size of the specimen that is tested. In the experiments which have been described the iron was a rod four millimetres in diameter. Smaller rods showed much less magnetic viscosity, and when a bundle of fine annealed iron wire was substituted for the rod, nearly all trace of "creeping" disappeared. The cause of this difference is at present obscure.

§ 90. **Molecular Accommodation.**—Closely related to the experiments which have been detailed in this chapter are results recently published by H. Tomlinson.* Examining the action of feeble magnetic forces, in the region within which the relation of **B** to **H** may be expressed (§ 86) in the form

$$\mathbf{B} = a\,\mathbf{H} + b\,\mathbf{H}^2,$$

he has discussed the influence of temperature and other conditions on the constants a and b. The constant a is of course the initial permeability, and it is on the value of b that the dissipation of energy depends. Some of the more interesting of Tomlinson's results may be briefly stated in his own words:—

"The internal friction of iron, nickel, and cobalt in any complete cycle may be decreased by repetition of the cycle; the molecules are said to be 'accommodated' by this process.

"The molecular 'accommodation' of freshly annealed iron can be largely aided by repeatedly raising the metal to 100°C, and then allowing it to cool.

"The 'accommodation' of the molecules of iron, nickel, and cobalt is disturbed by very slight mechanical shocks, by small change of temperature, or by magnetisation beyond certain limits; under such influences the internal friction may for a time, or even permanently, be considerably increased.

"The values of a and b for iron are temporarily increased when the temperature is raised from 0°C. to 100°C."

(To be continued.)

THE EDINBURGH EXHIBITION.—II.

Messrs. Smythe and Payne's Exhibit.

Amongst the exhibits of Messrs. Smythe and Payne, of Glasgow, at the Edinburgh Exhibition is an ingenious non-fusible safety cut-out. This cut-out makes use of the heating effect of a current without employing the high temperature necessary to fuse a wire. The principle of the device is as follows:—A conductor is employed, having a smaller sectional area than that of the wire forming the circuit which is to be protected; around this conductor is passed a cord made of a material which is easily charred or rendered brittle by the action of heat, and this cord holds in check a mechanical contrivance for breaking the circuit, which is controlled by a spring or a weight. When the conductor becomes overheated by an excess of current this cord gives way, releases the spring or weight, and allows the mechanical contrivance to come into action and break the circuit. This cut-out can be made in a variety of different forms, to suit the requirements both of high and low potential working. The figures shown will serve to illustrate the principles and construction of two out of a number which have been made. This device is also applied to switches themselves in such a manner as to render a separate cut-out unnecessary.

In Fig. 1 the contact bar B is centred at one end, a handle to work it being fixed at the other. If the cord A breaks, the hammer H, assisted by a spring S, knocks out the switch, which cannot be turned on again until the hammer has been drawn up and the cord replaced. A hammer, actuated by a spring, can be fitted to many different forms of switches, such as the circular pattern usually adopted for all the small single lamp switches. A good method of constructing a combination switch and cut-out is to employ some form of catch or trigger to hold the switch on; the catch is released by the hand under ordinary circumstances for switching off, but the operation is performed automatically by a spring or weight released by the attachment when there is an excess of current.

The form shown at Fig. 2 is designed to give a long break, and to ensure certainty of action, even though the contacts have become clogged with dirt and dust. Contact pieces, P_1 P_2, are fastened to the bar B, made of insulating material, and connected together by the conductor C. At both ends of the bar springs, S S, are fastened, which press against the contact-holders, H_1 H_2. The springy contact-pieces P_1 P_2 are

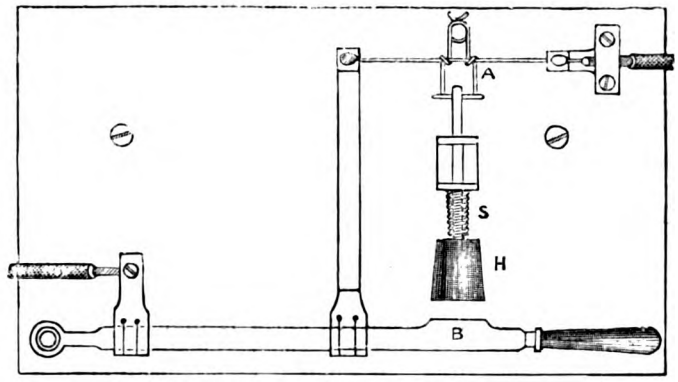

Fig. 1.—Smythe and Payne Safety Cut-Out.

pushed up into the holders, and held fast by the outward pressure of the toggles G G, made of insulating material. This pressure is due to the pull of the attachment cord A, which is secured to the toggles and also to the bar B, pressed downwards by the springs S S. When the cord which is passed round the conductor C gives way, the pressure on the contact-pieces, P_1 P_2, is removed, and the bar is free to fly out, thus leaving a break between the holders H_1 and H_2. The bar B can be replaced when the cord is renewed, without danger to the operator.

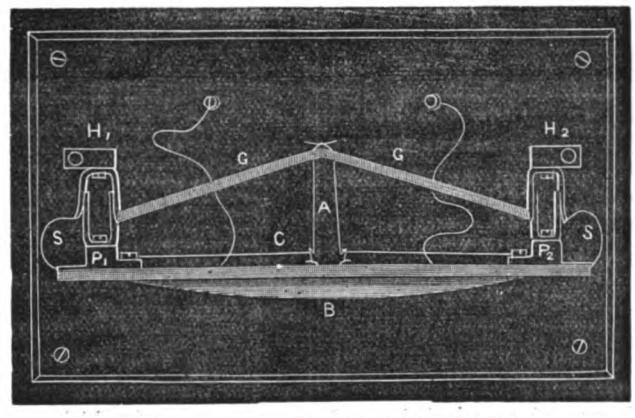

Fig. 2.—Smythe and Payne Safety Cut-Out.

The advantages of this form of cut-out are that there is no fusion of wires; the conductor can be soldered down and used over and over again. A new attachment cord is more easily procurable than a special fuse wire of the exact size and material required, which recommends the cut-out for ship-lighting. Some of these cut-outs are manufactured by Messrs. Fowler, Lancaster and Co., of Birmingham. Messrs. Smythe and Payne have carried on numerous experiments with a view to ascertain the best material for the attachment cord, and have tried jute, cotton, flax, hemp, silk, horsehair, leather, gut, and other cords. They find on the whole that gut answers the best, since it does not catch fire even if the conductor reaches redness before the cord breaks; it stands the continuous strain of the springs or weights, it gives way quickly and at a lower temperature than other materials, and is the least affected by

* *Proc.* Roy. Soc., December 5 1889.

Digitized by Google

moisture. In all the experiments made they state that they never saw a cord catch fire, although they tried coarse strings wrapped round fine wires, which had time to get red-hot before the cord was cut through. Fishing lines, which are made to resist the action of salt-water, make very good attachments, as they are strong and durable. By passing the cord spirally round the wire, as in Fig. 1, the sharp curves are avoided which might tend to snap the gut, especially where fine wires and strong springs are employed. The strain of the springs or weights is not directly on the wire, but on a peg or hook to which the cords are attached.

Exhibit of MM. Van de Plancke.

MM. Van de Plancke, of St. Nicholas (Waes), Belgium, have a large show of electric clocks. A reference to the annexed diagram will explain the arrangements adopted in this system. The diagram shows the movement for the regulator. An unequally weighted fly-wheel, A, fixed on the arbor C, keeps by the unequal distribution of the weight the same relative position with regard to the pins D E H when the wheel is at rest. Consequently, a sudden forward motion of the lever R, produced by the attraction of the armature K towards the electro-magnet L, causes the lever to strike violently against the pin E, and to turn the fly-wheel in the direction of the arrow. The second pin H passes underneath the lever R, and after the revolution of the wheel prevents the continuation of the movement coming again in contact with the lever, which is brought back to its first position by the spring S. The turning of the fly-wheel has the following effect. It winds at each interval of time, for instance, every half minute, by means of a pinion fixed on the arbor of the wheel, the spiral spring on the barrel as much as it has been relaxed on producing the motion of the clock during

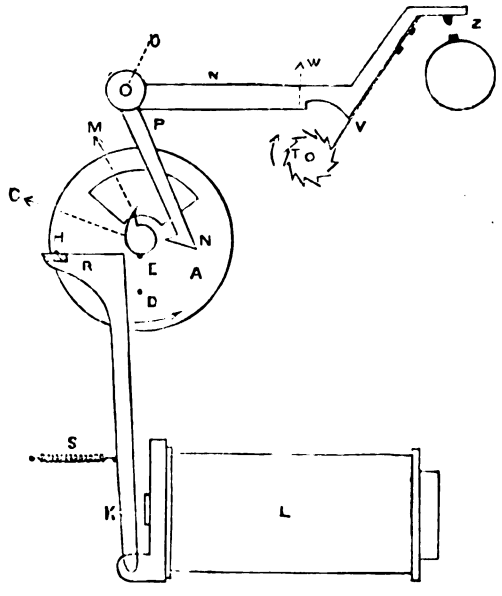

Fig. 3.

the same interval of time. It turns the cam M, which meeting the pawl N of the lever P lifts the latter and the lever N, both fixed on the axle O. This movement breaks the contact at Z, and allows the spring V to engage in the next tooth of the ratchet T. It also keeps the circuit broken. The ratchet wheel T, fixed on the middle wheel of the clockwork, moves in the direction of the arrow. The spring V, fixed on the lever N, pushes the ratchet wheel, and helps the movement until the notch W meets the next tooth. At this moment contact is made at Z. The electro-magnet attracts the armature, and the cycle of operations is recommenced. The movement of the receiving dials are constructed in much the same manner as the movement of the regulator. Every contact at the regulator sends the current into the coils of the receiving dials, and makes the hands move forward half a minute. One of the principal advantages of the system is the short contact, which is only $\frac{1}{8}$ of a second. Leclanché cells, wet or dry, can thus be used without fear of polarisation. There is but one contact in the circuit of regulator and receivers; and small and large receiving dials can work in the same circuit. A special form of regulator is constructed for the navy. In this form the required daily advance or retardation can be effected automatically in all the receiving dials throughout the ship.

A METHOD OF LOCALISING PARTIAL OR DEAD-EARTH FAULTS IN INSULATED CONDUCTORS.

BY H. CUTHBERT HALL.

This method is applicable to the elimination of faults from leads which have not been laid in pipes, or otherwise rendered inaccessible for manipulation.

The mode of procedure is as follows:—The cable in which the fault occurs is wound on an iron drum of special construction, as shown in the diagram below (No. 1). A is the barrel

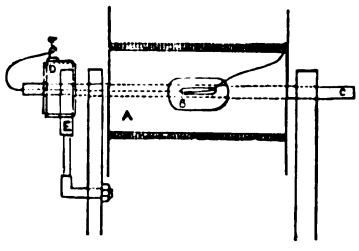

Fig. 1

of the drum, B an aperture cut in the barrel large enough to admit a man's hand, C a hollow tube which acts as the spindle of the drum. In C a slot about 10in. in length is cut, and to one end of C an insulated collector, D, is fixed. A brush E, also insulated, and fixed to the stand which supports the drum, makes contact with the collector D. One end of the cable to be tested is passed through the aperture B, threaded through the slot in C, and attached to a terminal on D. The other end of the cable is led through a vessel containing water and insulated from the ground, the cable being then wound on an iron drum, mounted on an iron stand. In diagram No. 2, Z represents the water vessel,

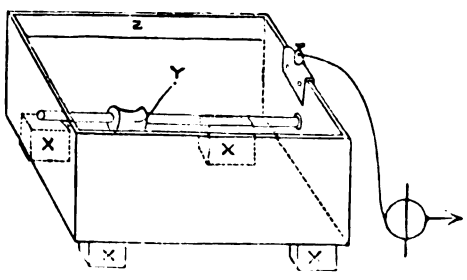

Fig. 2.

X, X, X, X, the insulating supports, and Y a pulley fixed under the water, and under which the cable passes. The end of the cable on A is connected to one pole of a battery by a lead, one end of which is attached to a terminal fixed to the brush, E. The other pole of this battery is put to earth. In the insulated water vessel, Z, a metal plate dips, to which is attached, by a terminal above the surface of the water, a lead connected to a Thomson galvanometer. The other side of the galvanometer is put to earth. While the fault or weak place remains on the drum, A, no deflection is obtained on the galvanometer; but as soon as the fault leaves the drum the galvanometer is deflected, this deflection being greatest at the moment when the fault enters the water. Thus a fault or weak place can be localised with great accuracy, even to a few inches.

The advantages claimed for this method are, that all cutting of the outside sheath of the cable is avoided; a great number of weak places in a cable can be localised in a very short time, the time occupied in detecting the faults being dependent only

Digitized by Google

on the speed with which the cable is wound from one drum to the other; faults of very high resistance can be localised with accuracy, any variation in the insulation resistance of different parts of the lead being at once apparent on the galvanometer. The test is not applicable to armoured cable, but has been used by the author with complete success with tape-covered, felted, and braided lead or cable. In the case of braided lead, this method of localising faults is of exceptional value, as the expense of repairing faulty braided lead is very much augmented by the fact that any cuts in the braiding have to be repaired by hand.

A distance of several yards between the first drum and the tank is advantageous, as the absence of deflection on the galvanometer, while the fault remains upon the drum, is dependent upon the resistance of the sheath of the conductor between the drum and the tank. Also it is desirable, for this reason, to have the cable as dry as possible before beginning to

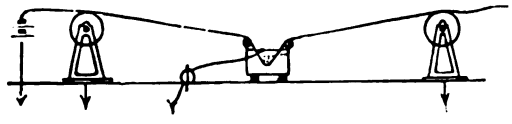

Fig. 3.

test. Neither of the above precautions is, however, essential to the test; but the best conditions for making the test are not obtained if these points are neglected.

In diagram No. 3 a general arrangement of the test is shown, which will make the above description more easily understood.

GELATINOUS ELECTROLYTES FOR STORAGE BATTERIES.

BY DR. PAUL SCHOOP.

An electrolyte for battery purposes is expected to be of high conductivity and to be constant during the use of the cell. Both conditions are fulfilled with a solution, particularly if it is kept in constant motion. As a rule the less fluid a solution is, the greater its resistance. But the fluid state of an electrolyte also presents disadvantages, at least from a practical point of view. The solution is easily spilled, it evaporates, its density becomes unequal. The dry cell has lately come into use for testing purposes on account of its transportability, though the capacity of it is inferior to the fluid cell.

For secondary batteries a solid electrolyte has even more importance than for primary batteries. As is well known, the storage of the current is effected by means of a spongy material, both on the positive and the negative plates; and it matters not whether this has been applied to the electrodes (or plates) mechanically or chemically. Practical experience shows that under ordinary circumstances the active material frequently drops out, and sometimes short-circuits the plates. If the cell is much shaken, as in the case of traction cells, the liability of detaching the active material becomes increased. Therefore, many efforts have been made to render the liquid solution more stiff; and sand, glass-wool, cellulose, asbestos-fibre, woollen-fibre, and saw-dust have been proposed. None of these substances have been used on an extensive scale, for the obvious reason that their absorbing power is not large; moreover, being non-conductors, these substances introduce a large resistance. But there are some bodies a very small quantity of which may convert fluids—water, for instance—into a solid mass. Glue, gelatine, agar-agar, starch dissolved in water (about 3 to 5 per cent. of the weight of the water) make it gelatinous. These substances have, of course, also been tried, but without success. Acids produce chemical reactions upon these bodies, and soon convert them into a fluid mass again; so also do some salts (chloride of zinc, for instance). No organic matter is likely to stand the action of the highly active oxygen developed by the electrolysis of water, even if it should stand the action of the sulphuric acid.

There is an inorganic substance, one of the most stable compounds known in chemistry, which has important gelatinising qualities, silicous acid. The salts of this acid, silicate of sodium and in a less degree silicate of potassium, are in common use. To obtain the gelatinous form of silicous acid, a dilute solution of silicum of sodium, say of 1·100 specific gravity, is mixed with dilute sulphuric acid of 1·200 specific gravity. Hydrochloric acid, or nitric acid, or nearly any other acid, will answer the purpose; also, all salts of ammonia, mixed with the solution of silicate of sodium, precipitate gelatinous silicous acid.

Suppose a storage cell has to be filled with gelatinous electrolyte. Three volumes of sulphuric acid, specific gravity 1·250, are mixed with one volume of silicate of sodium, specific gravity 1·180. The mixture remains at first perfectly fluid, but becomes more and more stiff and thick, and is gelatinous after two hours. After 24 hours the maximum stiffness is apparently reached. In charging the cell an interesting phenomenon is observed. As more current is taken up, so more water appears on the surface of the gelatine, and at last, when the cell is fully charged, a thin layer of acidulated water is on the top. This water disappears completely during the discharging of the cell, and the discharged cell is as dry as it was before. This process is repeated at every charge and discharge. The gelatinous mass is very elastic, and makes a perfect contact with the electrodes. If the latter develope gas bubbles (at the end of the charge or during over-charging) these bubbles force their way between the plate and the gelatine, pressing the latter back for a moment, and come out on the top of the cell. After the gas bubble has escaped, the gelatine at once touches the plate again and makes contact. This elasticity is one of the most satisfactory features of this gelatinised acid. The resistance of such an electrolyte is greater than that of the fluid dilute sulphuric acid, but the increase is not so important as to be a practical drawback. This will appear from the following tables, containing a charging and discharging of the *same* cell, filled at first with ordinary sulphuric acid (specific gravity 1·850), and afterwards filled with gelatinous acid, made in the manner described above. These numbers represent the average of half-a-dozen tests respectively.

Charging.—(*Cell Filled with Dilute Sulphuric Acid of 1·185 specific gravity.*)

E.M.F.	Amperes.	Hours.	Watt-hours.
1·94	...	...	...
2·08	35	...	...

Current constant at 10 amperes.

The cell in question consisted of seven positive and eight negative plates, each about $\frac{7}{64}$ of an inch thick; the weight of the plates (with paste) was 27lb., the weight of the electrolyte (in both cases the same weight) 17lb., the whole cell weighing about 46lb.

From the figures given in the tables it will be seen that the capacity of the cell with "gelatinous electrolyte" is only three-quarters of that of the same cell with dilute sulphuric acid. This seems at first a considerable drawback, but looking at the matter more closely it is not so alarming. The diffusion with gelatinised sulphuric acid, goes on slower than in the other case; and this is the reason: if the plates are chosen thinner, say, if 14 positive and 15 negative plates, each only half as thick as before, about one-tenth of an inch, and are put together as elements, the capacity of the cell with gelatinised acid is the same as has been found with the 15 thicker plates in ordinary acid. Practical experience has shown this, and also the reliability of such thin plates. But in fluid sulphuric acid, as it is known, such thin plates have a very limited life, on account of the support of the active material being insufficient. In this way, the resistance of the dry cell is also reduced to the usual figure, and it may be said that the distance between the positive and negative plates can be decreased as far as is necessary to overcome the higher resistance caused by the introduction of the gelatinising substance into the electrolyte.

Another point in connection with the "gelatinised electrolyte" is worth mentioning. It is known that the greater the rate of discharge the less is the available capacity of a cell. For instance, if the same cell which gives 250 watt-hours capacity (discharged with 10 amperes) is discharged with 100 amperes, it will be found to have only about half the capacity. That means that the acid already present *within the active material* is first used up, and *after* this only the acid which comes into the active material by diffusion or transportation of the ions. It can be stated that the accumulator with the greatest amount of acid, mixed with the active material, delivers the heaviest discharges for the longest periods. The utmost porosity of the active material is therefore desirable; but it can only be realised in combination with a solid material of sufficient elasticity to keep the loose powder in its place.

It would seem from these explanations that there is a large field for the use of gelatinised acids in connection with storage batteries. The certainty of working which results from the use of a storage battery has perhaps been the most powerful reason for its introduction in the electric lighting business, and yet this certainty is only relative. Short-circuiting, caused by the dropping out of the active material, has too often been a cause of trouble, not to speak of the breaking of a vessel. Gelatinised sulphuric acid avoids all this. After two years' practical experience no short-circuiting has occurred, and even cells in broken vessels have more than once done service for a week and more.

THE FRAGER ENERGY METER.*

The following is a brief description of the latest form of the Frager meter, an instrument which is largely used by the Paris electrical supply companies. The Frager meter consists of an electro-dynamometer, whose deflections afford a measure of the energy consumed, a clockwork arrangement which registers at stated intervals the energy consumed, and a train of wheels which show on a dial the product energy × time.

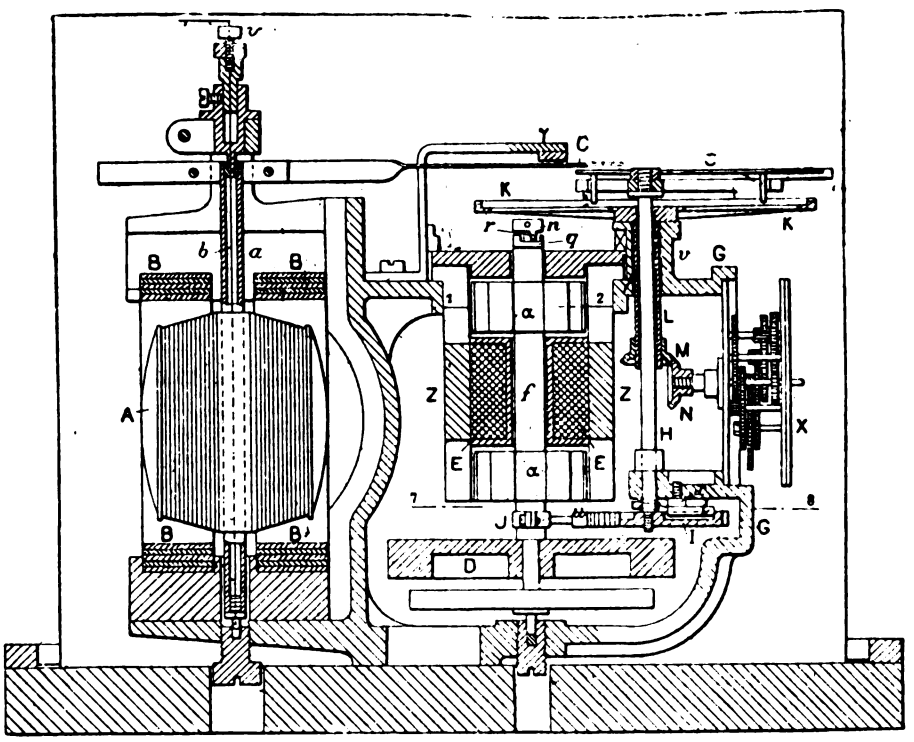

FIG. 1.—Frager Meter.

The electro-dynamometer consists of a fine-wire coil A (Fig. 1) divided into two halves. This coil is suspended from a torsion wire *b*, and is enveloped by the thick wire coil B B, which is wound in the reverse way to A. The torsion wire *b* is kept taut by the adjustable

* From *La Lumiere Electrique*.

Digitized by Google

screw *v*, and it is connected to the coil A through the tube *a*, which is rigidly attached to the frame of the coil and to the index needle C. The thick wire coil is in series, and the fine wire coil is in shunt with the lamp-circuit. The action of the fixed coil B upon the movable coil A reduces itself to a couple the moment of which may be expressed in terms of current intensity and a function of the angle between the axes of the two coils. As the moment of the opposing couple is proportional to the angle of torsion, the position of the index needle is a measure of the energy in the lamp circuit.

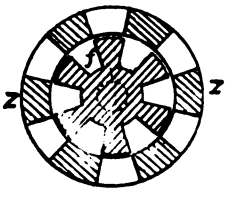

FIG. 2.

The clockwork mechanism is governed by a spiral spring seconds' pendulum, D, whose motion is maintained by electricity. To effect this the arbor *f* of the pendulum is provided with six projections (*see* Fig. 2), and moves freely within the hollow iron core Z of the coil E, which, together, constitute an electro-magnet with poles at *a a*. The coil E is connected at one end direct to the coil A, but the other end is connected to the other end of A through the spring *h* (Fig. 3). The arbor of the oscillating pendulum

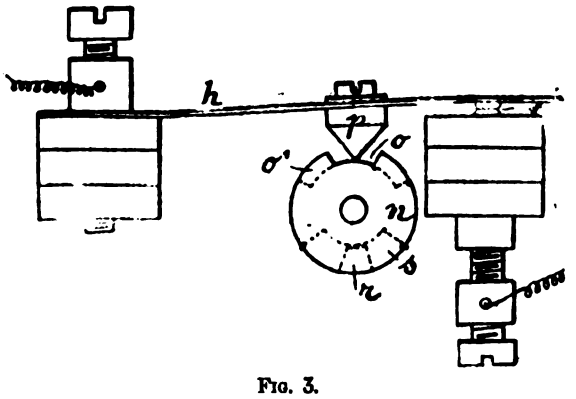

FIG. 3.

terminates in a cap, *n* (Figs. 3 and 4). When *n* is in the position shown in Fig. 3, the pin *p* falls within the notch *o*, and the circuit is completed through the contact *t*. Underneath *n* we have the loose disc *q*. This disc has a notch, *o'*, which is larger than *o*, and a cavity, *s*, in which oscillates the projection *r* (Fig. 4). When the pendulum D is in the middle of an oscillation, the teeth on the arbor, *f*, are in the position shown in Fig. 2, and the pin *p* falls within the notch *o*. As soon as the current passes the arbor rotates say to the right, the pin *p* is lifted out of the notch and the circuit is broken.

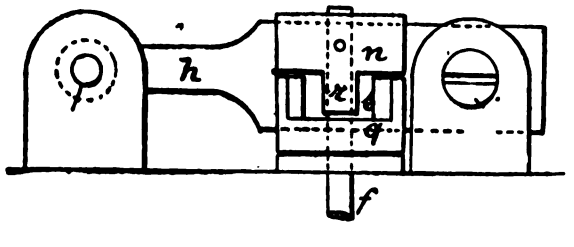

FIG. 4.

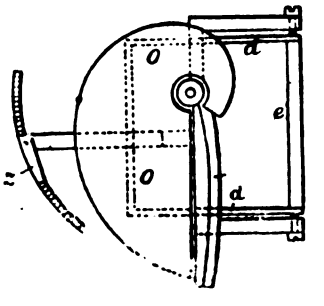
When the pendulum is swung back by the spring, the circuit is again closed, and the electro-magnet E gives it another impulse. This goes on until the amplitude of the oscillations is such that the pin *p* strikes against the other end of the notch. The average amplitude of the oscillations is therefore at least equal to the angle subtended by the notch *o*, and as the pin *p* falls within this notch at every half oscillation, the pendulum D receives an impulse every half oscillation. The object of the disc *q* is to prevent the oscillations from becoming too great. In fact, whenever the amplitude is greater than the play of *r* in the notch *s*, the cap *n* carries the disc *q* round with it, and if the amplitude of the oscillations becomes greater than *o'+s*, the ends of the notch *o'* lift the pin *p* and keep the current cut off until the diminution of the amplitude restores the notches to their proper relative positions.

The registering mechanism G (Fig. 1) is governed by the movements of the vertical arbor H, to which is attached the ratchet wheel I. The wheel I is provided with 100 teeth, and is actuated by the paw l J *u*, which causes it to turn through the distance of one tooth at every oscillation of the pendulum. The arbor H makes, therefore, one complete revolution in 100 seconds. At the top of the arbor H, there is a projecting piece which at every revolution lifts the end of the electro-dynamometer needle C against the circular piece *y* (Fig. 1). When the projecting piece passes from under C the needle falls upon the cam O (Figs. 1, 5, and 6) and depresses it, causing its support *d* to turn round *e*, so that the catch *z* being pressed into the notched edge of the wheel K brings it round with the cam O. The rotation of K is transmitted by *v* L M N (Fig. 1) to the counting apparatus X, and as the rotation of K is maintained during the whole period that the end of C rests upon the cam O, this rotation is proportional to the energy consumed. Hence the dial pointers revolve every hundred seconds by an amount proportional to the energy which is being consumed in the house circuit.



FIGS. 5 and 6

When at rest the axis of the coil A makes an angle of 45deg. with that of the coil B B. The scale is, therefore, very open near the position of rest, and the meter is, consequently, very sensitive for a small consumption. By altering the relative position of the two coils, the meter can be adapted to heavy circuits. When the relative exactness of the indications of the meter between the limits which it is proposed to use it have been ascertained, the calibration is completed by increasing or diminishing the number of teeth on the wheel I, according as the meter registers too high or too low, or by changing the wheel N (Fig. 1) the instrument can be converted into an ordinary current meter by merely replacing the coil A by a bar of soft iron.

Underground Telephone System at Berlin.—An extensive underground telephone system is now in course of construction at Berlin, and a large number of cast-iron pipes are being laid by the Telegraph Department for the purpose. The pipes, which are upwards of 25 miles in length, are to carry from 20 to 90 cables, and vary in diameter from 8 to 16 inches. The cables will be sheathed with iron wires, and contain uniformly throughout 28 conductors of No. 19 copper wire, insulated with impregnated fibre, and (to prevent induction or cross talk) lapped with tin foil. The cables now to be laid are over 90 miles in length, and have 2,520 miles of conductors. The cables are supplied by Messrs. Felten and Guilleaume. Man-holes (405 in number) will be placed at certain intervals for the purpose of facilitating drawing in of the cables and testing conductors. This extensive system, it is estimated, will cost about £100,000. It is hoped that when completed it will suffice for the ever-increasing number of subscribers, who already amount to 15,000. Messrs. Felten and Guilleaume, we may add, also supplied the telephone cables at Hamburg, mentioned in our issue of June 27th.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 5 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

THE THEORY AND PRACTICE OF ELECTRICAL ENGINEERING.

Of all branches of engineering the electrical enjoys the greatest advantage in the facility with which the principles of pure science can be applied direct to the work without the intervention of arbitrary coefficients and factors of safety which hamper most other professions. The hydraulic engineer, for example, takes the well-known formula for the discharge of water over a weir, and finds that he has to use a coefficient. He may turn to an account of measurements made by two highly skilled experimenters, published some four years ago, and there discover a bewildering page of coefficients according to authorities of every rank. At the end of the volume he will find a sheet of curves, which it is difficult to believe relate to the same thing; the dots through which, or rather among which, the curves are delineated resembling a map of the stars with the path of some eccentric planet that has lost its way. As another example, take the factor of safety of boilers. A factor of six is not unheard of; the Board Trade demand five for marine work; Lancashire boilers are generally made with a factor of four; while the land boilers in France have not shown by the number of accidents that the Government of that country are rash in fixing the factor of safety at three. What would the dynamo builder do if he had to allow such a factor in determining the dimensions of his field-magnets, his armature conductors, or his battery cells?

Electrical science started from the laboratory, and found its way to the workshop; mechanical science was developed for centuries by the empirical engineer, feeling his way from one venture to another, and relying more upon the accumulated experience of his craft than upon any rationalised principles,

Digitized by Google

uniformities, or inductions, which are called laws of science, until at last mechanical knowledge was reduced to mechanical science by Prof. WILLIS. It is not surprising, then, that electrical science shows at every point the touch of the theoretical man, and often to so marked a degree as to frighten the non-mathematical mind. The theoretical man is generally, but not necessarily, a mathematician; and until recently a mathematician has been a man who prefers to state a simple fact under the disguise of algebraical symbols, with an apparent love of mystery worthy of the Delphian oracle. The love of mystery is, happily, only apparent; he writes in his own language. The language of mathematics is thoroughly suited to the subject of electricity; and he who can guide his practical work upon mathematical lines will not go far wrong, though it does not follow that he will go in any useful direction or attain any profitable end. Engineers are generally led to some futile paradox, and always to a squabble, when they try to apply too much mathematics to the discussion of the steam engine, the theory of which is much more complicated than that of the dynamo, as its efficiency is less. While the electric engineer uses OHM's law perhaps many times a day, and relies thereon with the utmost confidence, BOYLE's law is a mere text-book matter to the engine builder, who prefers to use a calculated table rather than apply all the corrections and constants which are necessary.

There are some branches of electrical science, on the other hand, in which a very superficial use has been made of theory, the practical development having only received occasional hints from the principles and laws which bear on the subject. Storage batteries are an example of this. We are not aware that there is as yet a unanimity of opinion on the chemical changes which succeed each other in the process of charging and discharging; and it may be hoped that the Paper on this topic which is announced for the Edinburgh meeting of the Institution of Electrical Engineers will place the matter on a sounder scientific footing. Where chemistry and electricity meet there is a danger of falling between two stools; each science is so absorbing in itself that the border land between the two has been too often neglected. Electrolytic processes have been arrived at, generally by purely tentative experiments. Indeed, practice has so far outrun theory in the electric tanning method which we described a few weeks ago, that not even the able chemist who expounded, or rather conversed about it, on the occasion of our visit, could offer any theoretical hypothesis as to the action of the current on the liquor or the hides. Still more recently we were informed that there was no theory to account for the action of the buried rail of the latest electrical tramway, though it would be easier to suggest an explanation in the latter than in the former instance. The great inventor on the other side of the Atlantic has not, so far as we are aware, employed scientific methods of research, nor has he made use of the deductive method in the examination of particular cases, from previous knowledge of the principles of science which govern them. When the practical man goes first, blindly groping perhaps, but with some utilitarian aim, and produces an invention, the theorist takes it in hand, and often increases its value tenfold—witness the beginnings and the development of telegraphy. Nor does the reverse order yield less result, as in the history of the dynamo.

The unique position in which electrical science stands through having first been developed to a very considerable extent by the mathematician before any practical applications of it were made, should give it a firm foundation on which progress may be made with a confidence that no other branch of engineering can enjoy. A sound knowledge of the theoretical quantity of energy of any chemical combination, and the reliance which may be placed on that knowledge, together with a robust confidence in the laws of OHM and JOULE, would enable the youngest member of the profession to meet the wildest statements about lighting the City from a primary battery; and he would have an easier task than if he had to tackle an average inventor of perpetual motion. Unfortunately, our inductions can never be complete, and we never know when we are in possession of all the causes which apparently produce a given effect. Its sure foundation has enabled electrical science to make the more rapid progress; and this progress has brought about changes so great that we cease to wonder at them. Perhaps the worst evil that has resulted from this state of things is the advantage which has been taken of it by unscrupulous speculators in offering alluring baits to ignorant investors, for whom no wonder can be made too great to be swallowed if sufficiently flavoured with electricity.

OBITUARY.

LADY PENDER.

Great sympathy will be felt for Sir John Pender in the bereavement which he has sustained by the death of Lady Pender, who died on the 8th inst., after a very short illness. The loss will be deeply felt in the wide circle where her influence was felt. She was the daughter of the late Mr. H. Denison, of Daybrook, Nottinghamshire, and was the second wife of Sir John Pender, to whom she was married in 1851.

REVIEWS.

"Traité Th orique et Pratique des Machines Dynamo-Electriques." By R. V. PICOU. (Paris: Baudry et Cie.)

To give a complete theoretical and practical treatise of dynamo ma nines within the limited space of some 300 pages is obviously mpossible, and we need therefore not be astonished to find that the author of the book under notice has failed to carry out, in the strict sense of the word, the promise conveyed by the title. Nevertheless, he gives a good deal of theory and also some practical hints, though of the latter we should have been glad to see more. The author's position, as late engineer and present consulting engineer to the Paris Edison Company, must have given him and still give him exceptional opportunities of gaining information of a practical character; but at the same time it is easy to understand that, occupying the position he does, he cannot be expected to tell the reader all he knows on the subject; and this is, perhaps, the reason why the book, taken as a whole, is rather of a theoretical than of a practical character. But even theoretical books may be of practical use, and the work in point belongs to this class. It is certainly the best book on the dynamo which has as yet been published by a French author.

The book is divided into six parts, treating of the following subjects:—Elementary Matters in Connection with Electricity and Magnetism, Ideal Machines, Description of Machines as Actually Made, the Magnetic Circuit, Direct-Current Dynamos, Alternators. There is also an appendix treating of absorption and transmission dynamometers.

The chapters in which the author gives the elementary equations required for the study of dynamo-electric machinery form a kind of résumé of the matters usually found in text books, but no attempt has been made to show the connection between these equations and the ordinary mechanical laws familiar to engineers generally. Nearly all books which have

Digitized by Google

as yet been published on the dynamo fail in this respect. The authors seem to think it quite sufficient if they give the various equations for electro-magnetic relations which may be found in every text book, and leave the reader to find out, the best way he can, the why and wherefore of these equations and the manner of their practical application. To return, however, to the work under notice, those chapters in which dynamo machines are described might with advantage be enlarged. We miss nearly all the important English and German machines, while space is unnecessarily taken up with such obsolete machines as the Wilde, old Gramme, old Siemens, and Weston. There is, however, a fairly exhaustive description of the Desrozier machine, upon which no detailed information has hitherto been available. As regards alternators, the machines described are also mostly obsolete. We find here the old Alliance, Wilde, Siemens, and the very first type of Ferranti machine. Of modern machines the Zipernowsky and Westinghouse are the only examples cited, and their description is very meagre. Notwithstanding Mordey's experiments, the author still inclines to the opinion that iron in the armature of an alternator is necessary for parallel running.

After these descriptive chapters follow some on the magnetic circuit, on a general theory of dynamos, and on armature reaction, which doubtless constitute the best part of the book. Hopkinson's and Ewing's investigations are here summarised, and the author also gives some of his own results relating to hysteresis. The apparatus employed by him consisted of a wire coil, into which were inserted successively the different samples of iro to be investigated. An alternating current, which by me ıs of a rheostat could be kept of the same strength, was se through the coil, and the expenditure of energy was read off a watt meter. Unfortunately, the figures obtained are not directly comparable with those obtained by Hopkinson and Ewing, because Picou employed straight short cores, for which it is very difficult to determine the induction, which, moreover, must necessarily vary throughout the mass of the sample. It would in this respect have been better to employ samples of closed ring shape. The results have, nevertheless, considerable interest, as giving comparative values of the energy lost by hysteresis and eddy currents. The author has also investigated the effect of a change in frequency, and finds that in a particular case the hysteresis and eddy current loss is doubled when the frequency is trebled. Assuming that the hysteresis loss per cycle is independent of the frequency, he is thus able to separate from it the loss by eddy currents.

The author's theory of the dynamo is, as he states himself, a digest of the work done in this direction by Hopkinson, Kapp, Forbes, and Ewing. In developing the use of characteristic curves the author has, however, gone further than his English colleagues; and this part of the book will prove very useful. The application of theory to the designing of machines is shown by examples, and in selecting these the author has done his best to make his book useful to practical men.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

(Continued from page 230.)

§ 3. **Ganz Alternator.**—Proceeding, then, more particularly to describe the elements of the system, we take first the alternator, or alternating dynamo. The most recent type of Ganz machine, called the A type, is an alternator of that class in which the fixed or stationary electro-magnetic portion constitutes the armature, and the revolving portion the field-magnet. In Fig. 2 is shown a perspective view of the alternator, and in Fig. 3 face and end elevations. The field-magnet is a stellate electro-magnet, keyed on the steel shaft, which is the driving shaft. In the smaller sizes this shaft carries the usual pulley for belt or ropes keyed on outside the two massive bearings which are erected upon the bed-plate. A reference to Fig. 3 will also show how this stellate magnet is constructed. A number of V-shaped sheet-iron stampings (Fig. 4, *a*) are punched out and built up with interposed laminæ of paper into the cores, which are bolted in between two iron hubs or rings keyed into the shaft. These cores project like the stout spokes of a rimless wheel, and over them are slipped the magnet bobbins wound on split zinc frames. The bobbins are kept in position on the cores by a head or cap of gun-metal, which fits on the end of the laminated magnet core, and is firmly secured to it by a traversing bolt.

The magnet poles are even in number, varying from 6 to 40 according to the size of the machine, and are alternately north and south poles. Surrounding this stellate magnet is the ring-shaped armature frame, formed of two massive iron rings kept apart by distance pieces and bolted together. This armature frame carries on its inner circumference the armature coils. These, like the field-magnets, consist of cores built up of sheet-iron stampings, T-shaped (Fig. 4, *c*), which are held together by bronze press-plates and by bolts. On to these cores are slipped the armature bobbins, which consist of vulcanized fibre

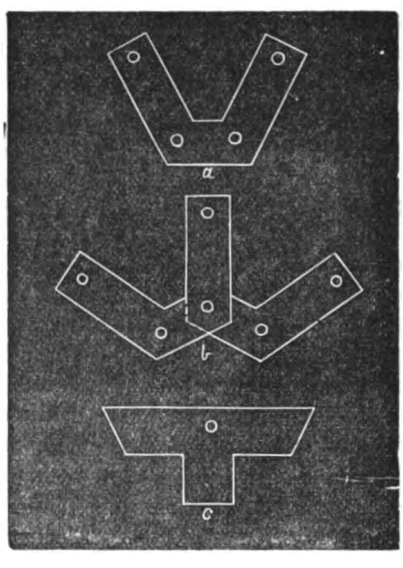

FIG. 4.—V and T-shaped Iron Stampings for building up field-magnet and armature cores.

frames, wound over with highly insulated wire. These bobbins are joined up in series in such manner that the currents induced in each are in the same direction, and generally one half of the armature coils is put in parallel with the other half, the individual coils in each half being joined in series. In like manner the several magnets of the field-magnet are divided into two sets, the magnet coils in each set being in series, and the two sets being joined up in parallel. The clearance between the polar faces of the field-magnets and the armature-magnets is very small. Each armature section is thus complete in itself, and can be removed or replaced in a few minutes. The armature sections are screwed to the distance-pieces of the main ring frame, but insulated from them by intervening insulating pieces. In building up the stellate electro-magnet core one layer of the V-shaped iron stampings is first arranged in the proper angular positions; another layer is then laid over them, with paper between, but so that the individual stampings of the second layer "break-joint" with those of the first, and the process continued until the proper thickness is obtained (*see* Fig. 4, *b*). Strong iron press-plates are then bolted up so as to compress all this mass of laminated iron into a star-shaped magnet. The bobbins having been put on the cores, the slightly projecting ends of the cores are fitted with bronze bobbin-holders, held on by a bolt which traverses the laminated pole, in order to prevent the bobbins from being thrown off when the magnet revolves.

* This series of articles is a continuation of those which appeared in *The Electrician* under the title of "The Alternate Current Transformer," by the same Author, and which have since been largely extended and republished in book form. All rights are reserved.

Digitized by Google

In some of the larger sizes of machines the annular armature frame is made to slide along the bed-plate in guide slots by means of a screw By this means the whole armature can be moved along laterally, so as to move it off the field-magnet, and enable this latter to be got at easily for repairs. The machines are made either to be auto-excited or separately excited. In the former case the excitation of the field-magnets is effected by a rectified alternating current. This current is supplied from the secondary circuit of a subsidiary transformer, whose primary is fed from the armature. The alternating current is rectified by means of a commutator keyed upon the shaft of the dynamo. This commutator is made in the following fashion:—On an insulating hub are arranged brass or copper cylindric sections, as many in number as the poles of the stellate field-magnets. These metal segments are insulated from each other, and separated by narrower metal sections insulated on both sides from the main sections. (*See* Fig. 5, in which the thick black lines represent the insulating portions

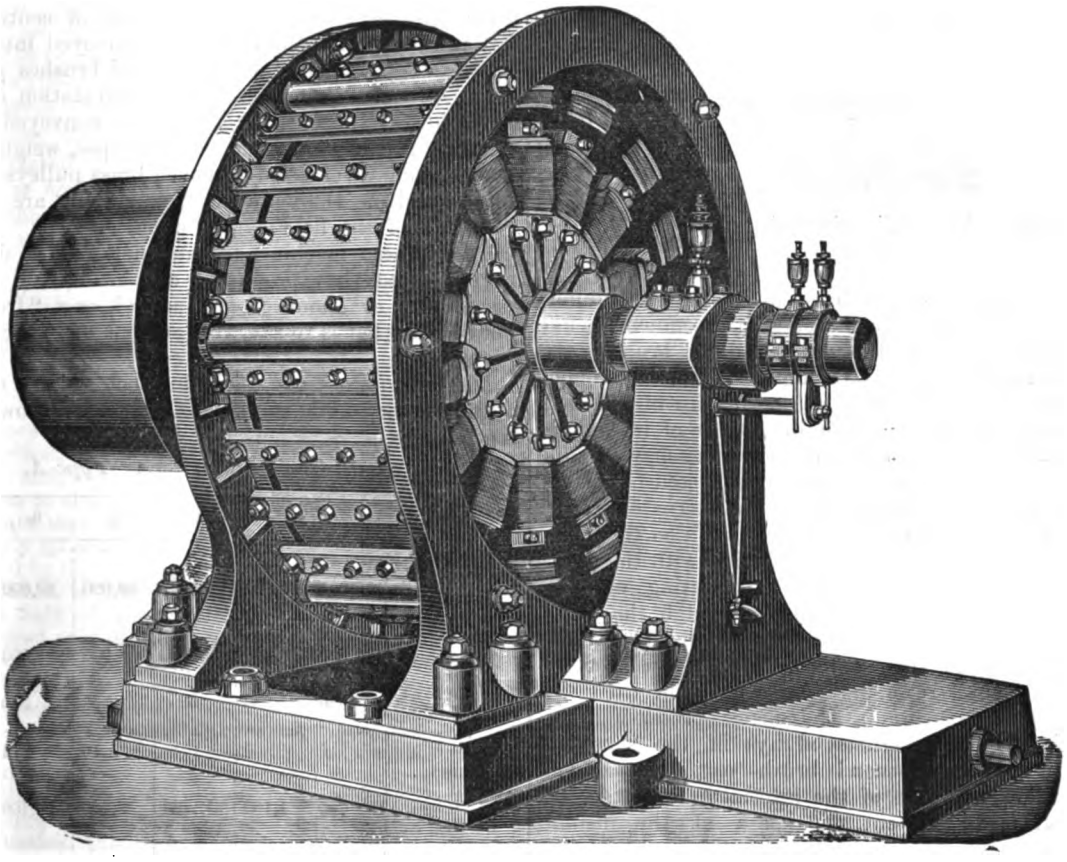

Fig. 2.—Ganz Alternator (Zipernowsky, Déri, Bláthy) 50 Kilowatt.

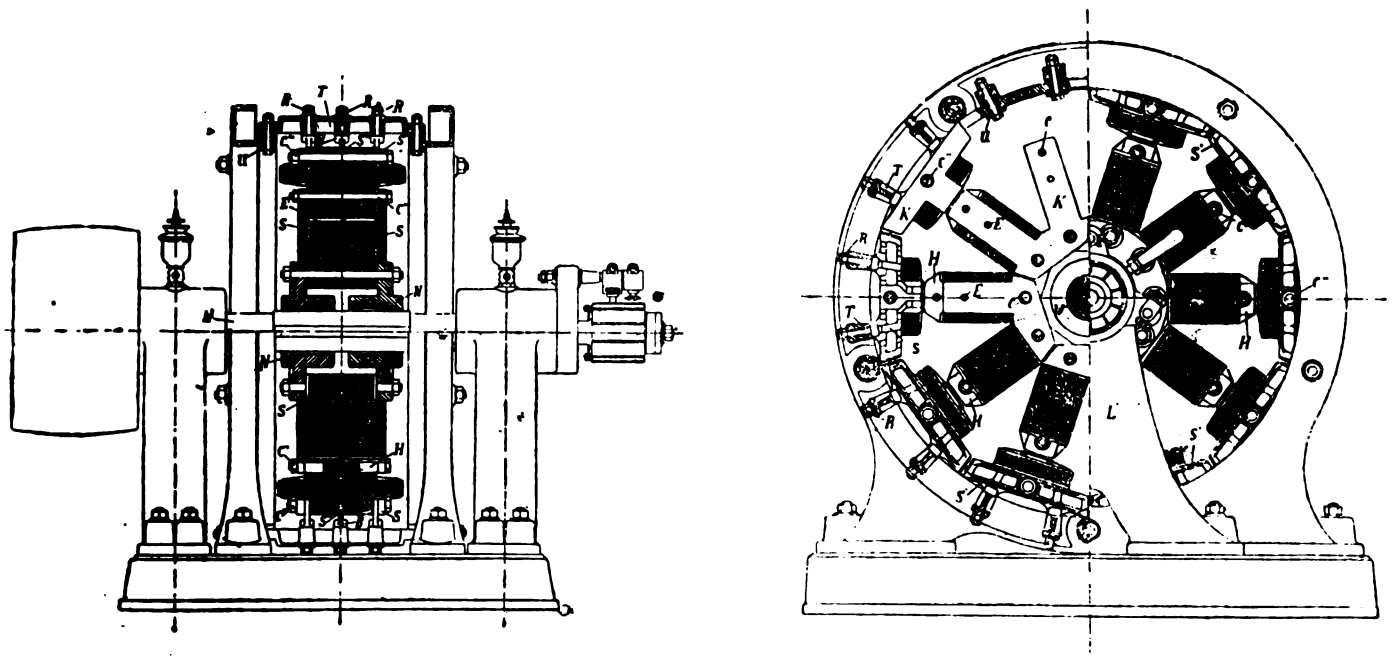

Figs. 3.—End and Face Elevations of Ganz Alternator.

Digitized by Google

(mica). The narrower sections are all connected together, and the wider sections are also so connected that alternate large sections are in conducting contact.

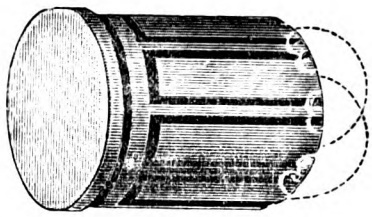

FIG. 5.—Commutator for rectifying alternating currents on Ganz Alternator.

In Fig. 6 we imagine the cylindrical surface of the commutator rolled out flat, the connections between the segments being represented by the firm and dotted lines. The brushes are represented diagrammatically in an oblique position. On opposite sides of the commutator there are two pairs of brushes, one brush at each side being a little in advance of its fellow. One set of the wide sectors, of which a member may be supposed to be in contact with one brush, is connected to the extremities of the field-magnet circuit; and the alternate sectors, one member of which is in contact with a brush on the opposite side of the commutator, are in connection with the other end of the field-magnet circuit. The alternating exciting current enters by one brush and passes through the field-magnet coils. As the electromotive force of the field transformer falls to zero and then reverses sign, so the sectors pass under the brushes, reversing the connection with the ends of the field-magnet circuit, and hence preserving the current through the field-magnets always in the same direction. The use of the second brush on each side in advance of its fellow, and also of the intermediate sectors on the commutator, is to prevent the spark at the instant when the brushes change sectors; and this is achieved by connecting through a little resistance the brushes on the same side of the commutator, one being a little in advance of the other, by an amount sufficient to place the one brush on the intermediate or neutral sector at the instant when its fellow steps off the "live" sector just behind it. At the instant, then, before the change of connection is made by the brushes leaving their respective sectors they are short-circuited

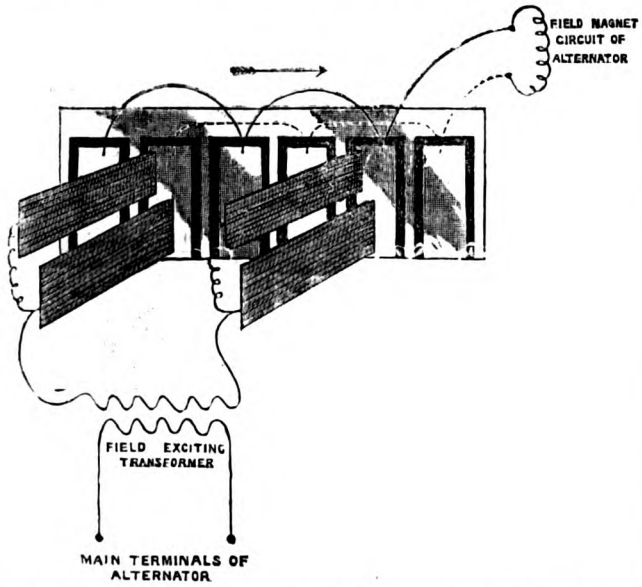

FIG. 6.—Diagram representing action of Commutator on Ganz Alternator.

by reason of the fact that their companion brushes are on the intermediate sectors, which are all in conducting connection. Hence the sparking, which would otherwise exist, due to the self-induction of the field-magnet circuit, is kept under, and the wear of the commutator greatly improved. This same device of a pair of brushes, one having a lead over the other to stop sparking, is employed in the Ganz alternating motor. (See *Electrician*, Vol. XXIV., p. 453, 1890.) The larger sizes of the Ganz alternators are not self-exciting, but are excited by a continuous current from a separate exciting dynamo. In the smaller sizes (150 horse-power) of central-station alternators the magnetising current is conveyed into the alternator by means of copper contact rings and brushes pressing against them. In the larger sizes of central-station alternators (600 horse-power) the exciting current is conveyed into the alternator by a pair of flexible copper ropes, weighted at one end, and hanging over deeply-grooved brass pulleys insulated from, but carried on, the main shaft, and which are respectively the terminals of the field-magnet circuit.

In all these machines the magnets are so designed that at normal speed they produce a current having 5,000 reversals per minute, or about 83 per second, or a "frequency" of 42 per second, that is to say, the current has 42 complete periods per second.

The alternators are made in about eight sizes, varying in output from 10,000 to 380,000 watts, as shown in the following table:—

Ganz Alternators.—Type A.

Number	1.	2.	3.	5.	6.	7.	8.
Maximum output of dynamo in watts.....	10,000	20,000	30,000	50,000	80,000	160,000	380,000
E.M.F. at terminals in volts ...	1,000	2,000	2,000	2,000	85,000	5,000	5,000
Revolutions per minute	830	830	625	500	360	170	125
No. of poles on field-magnet ...	6	6	8	10	14	30	4
Weight of machine in kilograms.	700	1,100	1,700	3,400	6,100	11,000	23,000
Maximum output of dynamo in watts.....	9,650	19,300	28,950	48,250	77,200	154,400	366 00
Horse-power required to drive dynamo at full load ...	15·6	29·8	44·1	76	120	233	550

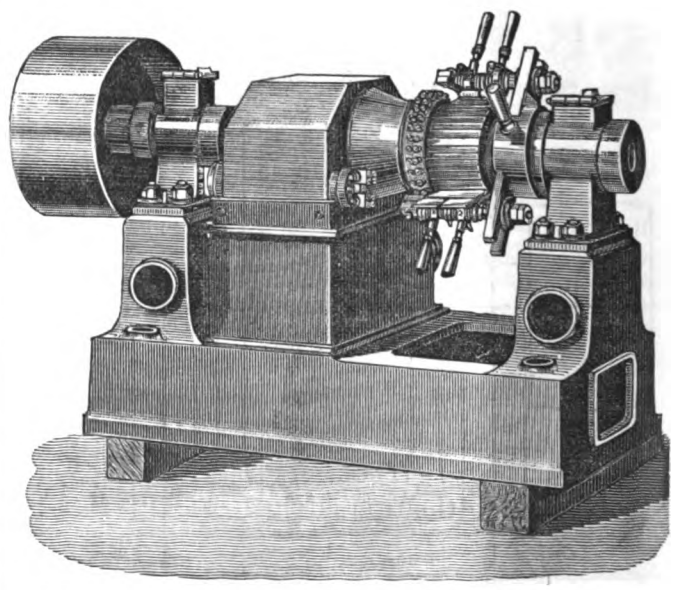

FIG. 7.—Continuous-current Exciter Dynamo, by Ganz.

The values here given for output and absorbed power are taken from catalogue figures, and must not, therefore, be regarded as having the weight and accuracy which might be expected from careful independent tests. They are here given merely for the purposes of general comparison.

Digitized by Google

The exciting dynamos employed in connection with the larger sizes of machines are ordinary drum-armature shunt dynamos supplying current at about 100 volts. The field-magnets are of the well-known form of vertical single horse-shoe type, and are illustrated in Fig. 7, and call for no special remarks. In some cases of central-station work the exciters are direct-driven by coupled engines, and in other cases they are driven by a belt off the alternator shaft. The general practice is to cause two or three alternators to feed into a pair of mains which supply the field-magnet circuits of the alternators arranged in parallel across them. By this arrangement a breakdown of one exciter does not interrupt the maintenance of the fields of the alternators.

(To be continued.)

THE ELECTRO-DEPOSITION OF PLATINUM.*

BY WM. H. WAHL.

The permanence and unalterability of the metal platinum have suggested its application as a protective covering upon the surfaces of other metals; and, even in the early days of the art of electro-deposition, efforts to obtain a satisfactory coating of this metal were made. The results that have been accomplished cannot be said to have been entirely satisfactory—a statement which, I believe, will be fully sustained by the fact that electro-plating with platinum, on the commercial scale, is practised only to a very limited extent. When the wide field of application for platinum-plating is considered—and I need only name philosophical, engineering, surgical, dental, and electrical apparatus and instruments, fire-arms, watch-cases, and jewellery, to say nothing of the host of miscellaneous articles of utility and ornament to which the metal could be advantageously applied—the conclusion is irresistible, that the processes thus far proposed for the purpose do not fully meet the requirements of practical service.

Thus far, of all the methods that have been proposed for electro-plating with platinum, three only appear to have sufficient merit to deserve special notice; these are:—

(1) Roseleur-Lanaux method, based on the electrolysis of a solution of the double phosphate of sodium and platinum.

(2) The process of the Bright Platinum Plating Company (of London), a modification of that of Roseleur, involving the introduction into the bath of certain substances, such as sodium chloride and borax, to ensure a bright deposit of the metal; and

(3) Boettger's method, founded on the electrolysis of a solution of the double chloride of ammonium and platinum in sodium citrate.

Each of these baths will yield satisfactory results for a time; but, as I shall endeavour to show, the peculiar difficulties met with in the practice of platinum-plating render it impossible to maintain the chemical integrity of these electrolytes, and, in consequence thereof, they soon become inefficient or inoperative by reason of contamination with the secondary products formed therein.

The first difficulty encountered is that of obtaining a bright, reguline and adherent deposit of the metal, in which form only it will answer the demands of practice. There is no difficulty in effecting the separation of the metal from solutions of almost any of its compounds. Zinc, iron, and tin reduce it promptly by simple immersion, and this very facility of reduction is one of the reasons why, even by the method of electrolysis, the desired object is frequently accomplished only in an imperfect manner; for the electro-plater is obliged to meet and overcome its obstinate disposition to separate from many of its compounds in the condition of platinum black, lacking coherence and adherence, and therefore entirely unsuited for his purpose.

Another, and no less serious difficulty, arises from the insolubility of plates or sheets of this metal as anodes, where solutions containing platinum salts are submitted to electrolysis. In electro-plating with copper, silver, gold, and nickel, but little difficulty is encountered in practice on this account, since anodes of these metals are freely soluble in many solutions capable of depositing them when they are submitted to electrolysis, and the rate at which these anodes are respectively dissolved approximates so nearly to that at which the metals are deposited upon the objects at the cathode, that the metallic strength of the electrolyte is maintained substantially uniform, and electro-plating solutions of these metals may be operated for a long time without requiring additions of metallic salts. The electro-deposition of the metals whose anodes are thus tractable is carried on industrially with success.

It results from this want of solubility of the anode that the metallic strength of the electrolyte employed is continuously being weakened, while the deposition of the metal is going on, and the conductivity of the bath is being continually modified thereby. The character of the deposited metal also is injuriously influenced by these constant alterations of condition in the bath; and, as the rate of deposition becomes slower and slower by reason of the gradual impoverishment of the metallic strength of the solution, it will be necessary to restore it by fresh additions of metallic salt. The practice in all the processes of electro-plating with platinum employed up to the present time, save that of Boettger, is to use for this purpose the tetra-chloride of platinum. With this single exception, all the solutions for the electro-deposition of platinum thus far made known, so far as I am aware, are made by treating the chloride with compounds of the alkalies, soda, potassa, or ammonia. Of these, the phosphates and oxalates of soda, or potassa, are in greatest favour, and a number of formulæ for preparing platinum-plating baths with their aid have been described. The resulting substance is commonly a double salt, such, for example, as the double phosphate of sodium and platinum; the double oxalate of potassium and platinum, &c., contaminated, however, in each case by the chloride of the alkali employed, which is formed from the decomposition of the platinic chloride. As often as it is found necessary to strengthen the bath, fresh additions are made of platinic chloride, which, by chemical interaction with the constituents of the bath, aided by the process of electrolysis, yields more alkaline chloride; and it follows that the bath, by reason of becoming surcharged with this foreign substance, and with other secondary products of electrolytic decomposition, ceases to yield bright, reguline platinum upon the articles to be plated therewith and must be discarded. It then becomes necessary to regain the platinum contained in the discarded bath by one or another of several processes of reduction known to chemists. The platinum thus regained may be converted into chloride and utilised in the preparation of a fresh bath, with which the same series of operations will be repeated. Boettger purposes to maintain his bath by fresh additions of his original solutions, but it must be apparent that the continued electrolysis of such a solution as he employs must be attended with the constant accumulation therein of alkaline chlorides from the same causes as those specified above. This rapid deterioration of the baths, therefore, involves their frequent renewal at the expense of time and labour, so that, in spite of the fact that there is a wide field for its application, it is principally for this reason that the art of electro-plating with platinum on the commercial scale has thus far been practised only to a very limited extent.

It was therefore necessary to devise some plan for overcoming the difficulties herein described; and, after making a number of fruitless experiments, I was so fortunate as to find a plan which appears to offer a solution of the troublesome problem of electro-plating with the group of metals, whose anodes are insoluble, in a more satisfactory manner than any other that has hitherto been suggested.

The plan here referred to consists in employing platinum hydroxide for the purpose of maintaining the metallic strength of the plating-bath. For this purpose, the hydroxide, which is readily soluble in alkalies and in many of the acids, may be introduced into the plating-bath from time to time and dissolved therein by stirring, or it may be permitted to remain in the bath in excess, the undissolved portion remaining at the bottom of the containing vessel, or it may be suspended in a canvas bag adjacent to or surrounding the anode of carbon, according as the nature of the electrolyte may indicate one or the other method to be the preferable one. As the solutions which yield the best results in plating are those of the oxygen salts, I have found it advantageous also to prepare these directly from the hydroxide. This method, I have found, is capable of yielding a number of electrolytic baths of platinum that will maintain their metallic strength approximately unimpaired during electrolysis, and without the objectionable features of introducing into them substances that will cause them to deteriorate by the accumulation therein of injurious secondary products of decomposition, as is the case where such baths are maintained by additions of platinic chloride or alkaline chloro-platinates, as has hitherto been the invariable practice. Referring now specifically to the properties that render the platinic hydrate useful for the purposes above indicated, the following points appear to be deserving of mention.

It is readily soluble in aqueous solutions of the alkaline hydrates, and in a number of acids, mineral and vegetable. In the treatment of the platinic hydrate with aqueous solutions of the alkaline hydrates, the former plays the part of a weak acid, forming compounds known as platinates, which are very soluble, and from which the platinum is not precipitated on the addition of an excess of alkali. A weak aqueous solution of sodic or potassic hydrate (but especially the last named) will dissolve a large quantity of platinic hydrate, at the ordinary temperature, though solution takes place more freely when heat is applied. These solutions have the advantageous features of being freely conductive of electricity, and of yielding bright, reguline, and adherent electro-

Digitized by Google

deposits of platinum on metallic surfaces previously prepared to accept the same. Furthermore, with a current of moderate strength, the platinic hydrate only is affected, as is shown by the pronounced evolution of oxygen at the anode and by the total absence of gas at the cathode. Also, it is manifest from the free solubility of platinic hydrate in alkaline hydrate, even in the cold, that if free platinic hydrate be present in a bath of alkaline platinate, the alkali set free in the process of electrolysis will combine with this platinic hydrate to form fresh platinate. For this purpose it will be necessary either to have present in the bath at all times a small excess of platinic hydrate which may remain upon the bottom of the containing vessel, without interference with the plating, and which may be replenished from time to time; or, to introduce at the end of the day's work, a quantity of the platinic hydrate sufficient to restore the metallic strength of the bath to normal, assisting the solution of the metallic hydrate by stirring, and if necessary by the application of gentle heat. As I have found that the platinate solutions act best when they contain a considerable excess of free alkaline hydrate, being more conductive of the current and yielding the platinum more freely and in the best condition, the addition of the proper quantity of platinic hydrate at the close of the day's work in the case of a bath of considerable volume, or the addition of small quantities at intervals, in the case of a small bath, will be found to answer the desired purpose of maintaining the metallic strength of the bath approximately normal for an indefinite period. In a bath where considerable free alkali is present, the platinic hydrate added as just indicated dissolves very freely even in the cold. The important fact is to be noticed, that the alkaline platinate solutions may be maintained and operated for a long time in the manner described, since no deleterious secondary products are formed by electrolysis to vitiate and render them inoperative, as will speedily be the case where the platinic chloride is used for this purpose. The mineral acids (hydrochloric, nitric, sulphuric, and phosphoric acids), dissolved the hydroxide freely, as likewise do certain of the vegetable acids, notably oxalic acid, and form with corresponding salts of the alkalies, double salts, many of which are soluble in water. Of the salts thus capable of being formed, however, so far as I have been able to determine by experiment, only a limited number appear to be adapted to yield a deposit of bright, reguline and adherent platinum. The halogen compounds may obviously be prepared more conveniently by the direct solution of the metal in *aqua-regia* than by the method I have described; but as I have found the oxygen compounds of platinum to yield much more satisfactory results, I therefore exclude them from consideration.

(To be continued.)

CONTRIBUTIONS TO THE MOLECULAR THEORY OF INDUCED MAGNETISM.*

BY PROF J. A. EWING, F.R.S.

After referring to Maxwell's discussion of Weber's theory, which ascribes magnetisation in iron and other magnetic metals to the turning of molecules which are already permanent magnets, and to suggestions made by Profs. Wiedemann and Hughes, and lately by Mr. A. E. Kennelly,† the writer describes experiments which he has made directly bearing upon the molecular theory. The experiments were made by grouping near to one another a large number of small permanent magnets, each pivoted on a fixed centre, and by studying the manner in which the configuration of the group changed when external magnetic force was imposed. The results do not support the notion that the molecular magnets form closed chains in unmagnetised iron. They lead, however, to the important conclusion that no arbitrary conditions of directional constraint need be postulated to make the manner in which the molecular magnets turn agree with the chief features of magnetic quality. In the writer's view the molecular magnets are perfectly free to turn in response to external magnetic force, except in so far as they are constrained by the magnetic forces which they exert upon one another. He discusses this theory in a preliminary manner with regard to the form of the magnetisation curve, the character of cyclic processes, the effects of temperature, of vibration, of stress, and so forth, and shows that it is in general agreement with the known facts. The summary of conclusions is as follows:—

I. That in considering the magnetisation of iron and other magnetic metals to be caused by the turning of permanent molecular magnets, we may look simply to the magnetic forces which the molecular magnets exert upon one another as the cause of their directional stability. There is no need to suppose the existence of any quasi-elastic directing force, or of any quasi-frictional resistance to rotation.

II. That the intermolecular magnetic forces are sufficient to account for all the general characteristics of the process of magnetisation, including the variations of susceptibility which occur as the magnetising force is increased.

III. That the intermolecular magnetic forces are equally competent to account for the known facts of retentiveness and coercive force, and the characteristics of cyclic magnetic processes.

IV. That magnetic hysteresis and the dissipation of energy which hysteresis involves are due to molecular instability, resulting from intermolecular magnetic actions, and are not due to anything in the nature of frictional resistance to the rotation of the molecular magnets.

V. That this theory is wide enough to admit explanation of the differences in magnetic quality which are shown by different substances, or by the same substance in different states.

VI. That it accounts in a general way for the known effects of vibration, of temperature, and of stress, upon magnetic quality.

VII. That, in particular, it accounts for the known fact that there is hysteresis in the relation of magnetism to stress.

VIII. That it further explains why there is in magnetic metals hysteresis in physical quality generally with respect to stress.

IX. That, in consequence, any (not very small) cycle of stress occurring in a magnetic metal involves dissipation of energy.

UNDERGROUND MAINS IN PARIS.

In our issue of July 12, 1889, we gave some particulars with regard to the system of underground mains employed in Paris by the Compagnie Continentale Edison, and more recently (*The Electrician*, Feb. 7, 1890) we described the system used by the Municipality.

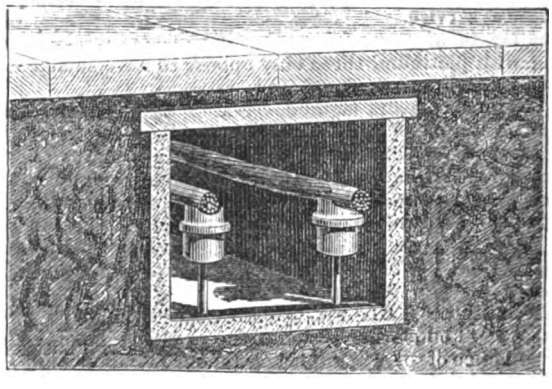

FIG. 1.—Underground System of the Société de la Transmission de la Force par l'Électricité.

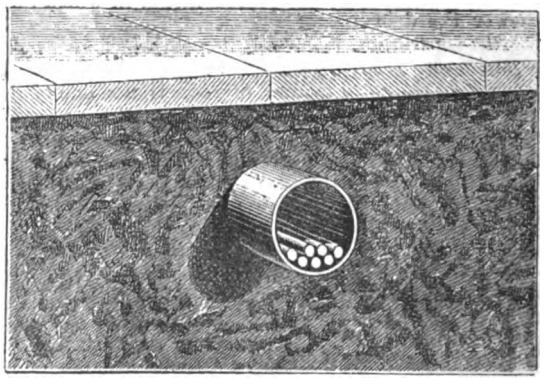

FIG. 2.—Underground System of the Popp Company.

The accompanying figures illustrate the methods adopted by two other companies engaged in the electric lighting of Paris. The Société de la Transmission de la Force par l'Électricité have at present three central stations, but these will shortly be converted into distributing centres fed from the main station at St. Ouen. A high-tension continuous current from St.-Ouen will drive motors in the sub-stations, the motors in their turn driving low-tension dynamos. The mains of this Company are of bare copper wire,

Digitized by Google

and are supported on porcelain insulators situated in cement conduits as shown (Fig. 1). The conductors are kept on the insulators by galvanised iron cross-pieces. The Compagnie Popp employ iron pipes 20 cm. in diameter (Fig. 2). These pipes are provided with flanges, and the lengths are bolted together, a ring of india-rubber being placed between the two flanges as they are screwed up. The cables, which are insulated, are drawn in in the ordinary way. We are indebted to *l'Électricien* for the above particulars and illustrations.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—THURSDAY, July 3rd.

Central London Railway Bill.

The Select Committee of the House of Lords, presided over by Lord Henley, resumed the consideration of this Bill on Thursday, when further evidence was taken in support of the case for the promoters.

Colonel HEYWOOD, engineer to the Commissioners of Sewers of the City of London, examined by Mr. Saunders, Q.C., said he did not know what would have happened at Cheapside if Victoria-street had not been made. Notwithstanding the formation of that street, as well as of Cannon-street, and the increased number of passengers carried by the railways, the traffic in the streets of the City was increasing rapidly, and causing great public inconvenience.

Mr. H. P. GILBEY (senior partner of Messrs. W. and A. Gilbey, the Pantheon, Oxford-street) said that in his opinion the proposed railway would be of the greatest possible advantage to those carrying on business in Oxford-street, as it would relieve the congested traffic of the street. The Committee again adjourned.

FRIDAY, July 4th.

Sir JOHN FOWLER, one of the engineers to the proposed railway, was examined by Mr. Pember, Q.C. There would be no damage done to St. Paul's Cathedral by the construction of the railway. He considered the capital sufficient; the railway would be cased in iron, and about 70,000 tons of that metal would be used. As there might be a fluctuation in price of £3 or £4 a ton, it was necessary to have a considerable margin of capital. He did not think the margin was too large. He was very anxious in this case to have sufficient capital, in order to avoid that which had damaged so many other undertakings.

Sir FREDERICK BRAMWELL also gave evidence in support of the Bill.

MONDAY, July 7th.

The Committee on this Bill resumed their inquiry at the House of Lords on Monday, when Mr. Joseph Keech Aston (secretary and treasurer to Queen Anne's Bounty), Mr. Binnie (surveyor to the County Council), Mr. W. Malleson (carrying on business near Holborn-viaduct), and Sir George Bruce (past President of the Institute of Civil Engineers), gave evidence. Mr. Bidder, Q.C., and Mr. Cripps, Q.C., addressed the Committee, which afterwards adjourned, in consequence of the illness of Lord Rowton, one of the members.

The Telephone Companies.

The DUKE of MARLBOROUGH called the attention of the House to the fact that the period within which Her Majesty's Government can serve notices to terminate the existing licences to the National Telephone Company expired at the end of last month, and to move—"That in consequence of the recent declaration of the Postmaster-General, in another place, that the Post Office do not intend to undertake the work of the telephone as a branch of that department, it is advisable that licences be granted to responsible parties who will be willing to undertake the business of forming new telephone companies on the expiry of the present patents owned by the National Telephone Company; and that competition is advisable in the interest of the public in order that the present exorbitant rates may find their proper level." The noble Duke said that, in answer to questions he had put in that House, the Marquis of Salisbury had said that the matter was one of great public importance, and that it would be considered at some time during this year, and afterwards the noble marquis had said that the matter was under the consideration of the Government, who had not come to any decision as to the line they would adopt. Subsequently, in the other House, the Postmaster-General was asked whether the Government intended to exercise their powers to buy up the licences and the telephones; and the answer was that the Government had no such intention. The question arose whether the admission of the Prime Minister that the matter was one of great public importance did not call for some further statement on the part of the Government. Their lordships must be more or less familiar with the uses to which telephones could be and were applied. There were telephones in nearly every considerable town on the Continent. In Paris there must be three or four times as many subscribers to telephones as there were in London. The comparative absence of telephones in London was partly due to the amount of money paid for patents and in the formation of companies, and partly to the want of facilities for extending the operations of the companies. When the telephone was first introduced the Company owning it obtained a peculiar licence from the Government. It was a licence for 30 years to carry on business under certain restrictions and regulations, and the Government reserved the power to buy up the interests of the companies every seven years on giving a prescribed notice. The Company agreed to pay to the Post Office a royalty of 10 per cent. of their gross receipts, and the Company undertook that they would neither sell nor assign nor dispose of their powers without the consent in writing of the Postmaster-General. Any difference of opinion between the Government and the companies as to the valuation of their property was to be settled by arbitration; and the valuation was to include powers, privileges, works, and other property, but nothing was said as to plant, goodwill, or unearned increment. As the Government did not give the prescribed notice on June 30 last, to expire on December 31, it would now be December, 1897, before they could acquire the telephones. No one with any practical experience would venture to say what the Government might be called upon to pay, whether it would be one million or four millions. It would be a public benefit if the Government would acquire the whole telephone system at a cost of two or three millions, so as to enable them to enlarge the facilities for inexpensive telephonic communication; but as the Government would not do this, the public must look to the present companies. The United Telephone Company, which obtained the licence from the Government, had paid high dividends, and they had pooled their interests with other companies. This company possessed all the Bell patents, for which they paid £370,000. The Company formed subsidiary companies—the Lancashire and Yorkshire, the National, and one or two others—each of which had its own capital. When the telephone was proved to be a success, the shares of the United Company went up from £5 to £15; and the shares of the subsidiary companies, in which the original company had large holdings, also advanced considerably. A remonstrance was issued by the Postmaster-General against these transactions, which was in direct contravention of the clause in the licence against the sale or assignment of the Company's interests. The charge for a telephone in London was £20 a year, whereas the average charge for one in all the European capitals was £6 a year, and the English telephones being connected with single wires only were so subject to inductive and other disturbances that they were practically useless. To make them of real value they should be worked by means of double wires. If the houses in the West End had a good telephone service it would save an enormous amount of correspondence; but in order to obtain an efficient service there ought to be competition. In the face of the agreement that the Postmaster-General had entered into with the National Telephone Company it would be most unfair, most unjust, and most improper for his department to enter into competition with the existing telephone companies; but that was no reason why he should not grant licences to new companies who would probably make use of improved telephone systems much to the public advantage. Notwithstanding the fact that the National Telephone Company's capital had been what was vulgarly termed "watered" to the extent of £2,000,000, the price of their shares was still going up, which showed that the telephone business was a very paying one. He thought that the House was entitled to a clear statement on this subject from Her Majesty's Government as to what policy they intended to adopt with regard to telephones in the future. He should like to suggest that the Postmaster-General should keep the main telephone lines throughout the Kingdom in his own hands, and should allow various companies to supply the local demands. He begged to make the motion which stood upon the paper in his name.

The EARL of JERSEY said that the subject to which the noble duke had called attention was one of considerable interest, because any improvement in the means of our communication was always welcome to the public. It was not necessary that he should follow at any length the remarks of the noble duke, neither did he feel called upon either to defend or to attack the existing companies. He had observed that the noble duke had placed a construction upon the answer of the Postmaster-General in another place which it could hardly be said to bear. The Postmaster-General had said that the Government did not intend to give notice to purchase the undertakings of the telephone companies at the end of the year, but that answer did not debar the Post Office from undertaking telephonic work in cases where it might be thought necessary or desirable. The Government did not intend to adopt the policy of purchase by the State of the telephone companies. To do so would be to involve the State in a gigantic enterprise into which the Government were not prepared to enter. The Government intended to grant licences to new companies which might apply for them; but, of course, each company would have to show that it was able to undertake the work for which it applied. The most important patent rights which gave a sort of monopoly to the present companies would expire in the middle of next year, and then competition would most likely arise, and in that way the public would reap with the least risk the benefits which the noble duke anticipated. He trusted that the noble duke would be satisfied with the statement he had made, and would withdraw his motion.

The DUKE of MARLBOROUGH then asked leave to withdraw his motion.

The motion was by leave withdrawn.

Electrical Lighting Orders.—In the House of Lords on Tuesday last, on the motion of Lord Balfour of Burleigh, the sessional order against a Provisional Order Bill originating in that House being read a first time after May 16th, was dispensed with in respect of a Bill to confirm certain Provisional Orders made by the Board of Trade under the Electric Lighting Acts 1882 and 1883, relating to Aberdeen, Dundee, Kelvinside, and Moss-side and Stretford; and the Bill was brought in and read a first time.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 27, 1890.

The New York Municipality and the Electric Light Companies.—The usual row between the City authorities and the electric lighting companies is especially lively at present. Last April, when the bids for street lighting were put in, the electric lighting companies of one accord raised their prices, owing to the immense expense and great inconvenience to which they had been put by the action of the city in the matter of subways. At its last meeting the Gas Commission called for new bids to be open early in July, making the usual threat of going back to gas lighting in case the service should not be furnished on terms more favourable to the city. It is well known to those acquainted with the cost of electric lighting in this city that the increase in price asked for is not without reason, and that the new schedule cannot fairly be considered excessive. It is quite clear that the public will not tolerate the abolition of the electric light, and a return to the dismal apology for lighting furnished in former years by gas.

High Efficiency Transformers.—At the last meeting of the Institute of Electrical Engineers a couple of clever Papers were read bearing upon the efficiency of the alternating-current transformer. The results obtained were very high, 96 per cent. being the efficiency on normal load and 90 per cent. on all-day working. These extremely high figures would almost lead one to suspect some constant experimental error, and it is to be hoped that the investigators will take pains at some future time to check the result by a change in the methods of work.

Gas and Steam-pipe Explosions in New York.—During the past few weeks New York has experienced several severe gas and steam-pipe explosions. The most striking of these I noted in a previous letter; but the subsequent ones have done no small amount of damage to tradespeople and manufacturers. Lower Broadway and adjacent streets are undermined by pipes of every description, where gas mains and steam heating mains vie with each other in doing indiscriminate damage. The reports of the City engineers are specially severe on the New York Steam Heating Company, and unless it amends its ways immediately they recommend that steps should be taken to revoke its charter, on the ground that its business, as now conducted, is a common nuisance. The electrical subways have been special sufferers at the hands of these obstreperous neighbours, and it is exceedingly difficult to maintain insulation on underground wires anywhere within the range of operations of the Heating Company.

Lightning in the Manhattan Company's Station.—A notable exhibition of electrical enterprise occurred the other day, when a severe thunderstorm broke over the city, and the lightning entered the station of the Manhattan Electric Light Company, and left only two or three valuable dynamos out of a total of more than thirty. A very large amount of damage was done; but the work of reconstruction began immediately, and the night after the fire one half the arc lights and 12,000 incandescents were turned on as usual, and by the succeeding night 17,000 incandescents were in regular use. Other electric lighting companies turned in to aid their unfortunate competitor, and the damage was very rapidly repaired.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *July* 8, 1890.

Mention has frequently been made in your columns of the curious system of electrical distribution adopted by the Popp Company; but it is of such a unique character that I think it worth while to again call attention to it. At the present moment the Popp Company have commenced work upon a gigantic system of mains upon the left bank of the Seine. When M. Victor Popp, some little while ago, obtained the 40 years' concession for the distribution of compressed air for the purpose of driving automatic clocks, he succeeded in getting a clause put into his contract to the effect that his compressed-air system could be employed not only for the purpose of working clocks, but in connection with any kind of machinery. It is in virtue of this clause that Mr Popp is to-day laying his vast system of compressed-air mains for driving dynamo machinery.

The station in the Rue de Saint Fargeau has a capacity of 600 horse-power, and produces daily 550,000 cubic metres of compressed air at a pressure of six kilogrammes per centimetre (85·8lb. per square inch). The station now in process of construction on the left bank is situated close to the Orleans railway station. The pipes are being laid in special conduits placed under the pavements. The mains on the left bank will be connected with those on the right at the Bastille and at the Place de la Concorde. An additional station in the Boulevard Richard Lenoir will be connected with the general system. These three stations will supply compressed air to 28 sub-stations, established in various districts of Paris. In the sub-stations the compressed-air motors with steam heaters will drive dynamos which will charge accumulators, and it is only after this long series of transformations that electrical energy will be distributed to the consumers. The works connected with this gigantic, though somewhat irrational scheme, are being pushed forward with great vigour, in the hope that they may be completed by November next.

The provisional station of the Compagnie Continentale Edison, in the Avenue Trudaine, is nearly complete, but the permanent station has made but little progress. The system of underground mains differs somewhat from that laid down along the Grand Boulevard. As previously, bare copper strip is used; but in order to get more conductors into a given space, they are arranged side by side on notched porcelain bridge pieces and also in vertical layers. This arrangement enables a much larger number of feeders to be laid in the small conduit.

At the last meeting of the Société Internationale des Électriciens, M. de Nerville read a Paper on some photometric tests, which he had carried out with M. Lepage and the students of the Laboratoire Centrale. He has ascertained that in the boxes of theatres the mean luminous intensity is 20 bougies, and in ball rooms 30; while at an ordinary writing table 30 bougies are also wanted. On a bright moonlight night the average illumination of the ground is ·33 bougies.

CORRESPONDENCE.

THE MAGNETIC CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read your criticism which you publish in this week's issue. I am not able to understand its meaning. In my article I say nothing about magnetic currents, neither do I hint even that magnetic resistance involves heat waste. For many minutes I have tried to picture in my mind a "magnetic current," and I have failed. The magnetic induction is, however, of the nature of a flux, and has a rate of fall of potential. I do not agree with you that I have chosen the wrong analogy. Oliver Heaviside may have "properly worked out" an electrostatic analogy, but that is no proof there are no other analogies to be found. It is impossible to make any analogy "go on all fours;" and the electrostatic analogy fails at some points as much as any other. For instance, the number of lines of *force* radiated from unit magnetic pole is *independent* of the medium, *i.e.*, the stress is independent; while the stress between two charges is *eminently affected* by the dielectric. Again, in electrostatics, where is the analogue of $B \div H$?

I am familiar with the writings of Oliver Heaviside, and have enjoyed reading them. But I have not yet come across any warrant in them for the statement that there is no analogy between magnetic flux and electric currents. If it is true, and there is no analogy, all my paper is nonsense, and quite unfit for publication; but *if my* EQUATIONS *are correct* (and they are) there *must* be an analogy as far as these equations go.—Yours, &c.,

E. T. CARTER.

School of Electrical Engineering, 12, Prince's Street, Hanover Square, July 5, 1890.

[We comment on this letter in our editorial columns.—ED. *E.*]

PRIMARY BATTERIES FOR LIGHTING PURPOSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent "Electromaniac" gave last week some *primâ facie* reasons in support of his belief that chemical batteries may some day "triumph over steam;" but he omitted

Digitized by Google

one very important consideration, viz., that in a primary battery no part of the ingredients used to produce the electric current is lost or "consumed." While producing that current, both zinc and acids undergo changes of composition, the zinc is oxidised and dissolved, the acids are diluted and their acidity weakened; but both retain all that is necessary to allow of their being recovered as valuable commercial products.

If the battery is properly handled, the oxidation of one ton of zinc will produce 1,340 electrical horse-power hours of current, giving in glow lamps the light of 333,000 candles, and in arc lights 1,665,000 candles, which last is 55 times as much light as can be produced from one ton of coal, or 10,000 cubic feet of gas. It can then be wholly recovered as sulphate of zinc crystals by an extremely simple and inexpensive process; and these can again be converted, after oxidation, into metallic zinc, and used over and over again in the battery. The spent acids I convert into dry agricultural fertilisers exceeding in value the richest Peruvian guano.

Your article last week on the gas companies as undertakers of electric lighting (which, however, are in many cases precluded by their statutes from supplying electricity) leads up to the further consideration that the Gaslight and Coke Company provides for an annual dividend of 13 per cent. on the whole of their £5,500,000 of ordinary share capital by means of the sale of their residual products (coke, ammoniacal liquor, and tar), because that circumstance suggests analogous results from the use of chemical batteries to produce electric light, whereas dynamos and steam-engines furnish no residual products applicable to such a purpose.

Again, when recently commenting on the fire which occurred at the house of Mr. R. D. Sassoon, you remarked that the circumstances as described "would point to the presence of a high potential current in the house circuit," and there may probably occur many unlooked-for accidents when London is generally supplied with electricity by currents of the dangerously high potential which the chief companies contemplate employing. But no such risks could possibly occur with primary batteries; for even those which I advocate for the supply of groups of houses and large buildings, lighting, say 1,000 lamps, would only need to be worked with the very low pressure necessary for sending the current over mains two or three hundred feet long, and through the lamps all in parallel.

The internal resistance of the cells, to which "Electromaniac" alludes, becomes almost inappreciable with currents of 1,000 amperes from each cell (multiple cells I mean, such as I use), for with $\frac{1{\cdot}8}{1000}$ we have R = 0·0018. Between the ranges of 19 and 22 cells for lamps of 10 candle-power, such a battery may be worked with a nearly uniform E.M.F. (maintained automatically), even when varying the number of lamps in circuit from 5 up to 1,000.

The cells can be easily filled and emptied from one point of supply much as your correspondent suggests, and I entirely agree with your own observation that any trusting to domestic servants should be rigorously avoided.—Yours, &c.,

O. C. D. Ross, M.Inst.C.E.

15, Relf-road, East Dulwich, July 9, 1890.

[Our correspondent encloses a hypothetical table, showing how six groups of 22 cells may be arranged to supply 1,000 lamps of 10 candle-power, with a nearly uniform pressure of 33 volts.—Ed. *E.*]

ACCUMULATORS WITH POROUS PARTITIONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of July 4th, under the heading "Accumulators with Porous Partitions," it is stated that M. Chatiliez has written to *L'Electricien* to say that he has met with considerable success by employing ordinary porous partitions between the battery plates. In case your readers should think that this method of applying the ordinary porous partitions is novel, I write to inform you that I have, in connection with the installation at my private residence, for the last eighteen months used these partitions in a similar manner—both plain and perforated—and I consider them in all respects satisfactory. —Yours, &c., Pearson Goward.

BRIGHTON ELECTRIC LIGHTING.

A special meeting of the Brighton Town Council was held yesterday to receive a report from the Lighting Committee, with tenders for the erection of buildings for an electric light generating station, and for supplying and fixing machinery and plant and laying cables for the supply of electricity to a portion of the borough.

The abstract of the Committee's report, which we give below, was published in the leading local paper on Monday last.

The Local Government Board having sanctioned the loans applied for by the Council for the purposes of the electric lighting station and works—namely, £2,500 for the site, repayable within a period of 40 years, and £30,000 for the works, repayable within a period of 25 years—the Lighting Committee beg herewith to submit tenders for carrying out the works. The Committee also report that in consequence of some rights to ancient lights on the east side of the site which have been found to exist, it has been necessary to revise the plans for the generating station, and some other modifications which the Committee deemed advisable have at the same time been adopted. The Committee have invited the contractors who tendered upon the original plans to send in offers for the work as now proposed to be carried out, and the amended plans with the new tenders are submitted herewith. On considering the tenders for the boilers (Section B), the Committee have come to the conclusion that it is advisable to have a third Lancashire boiler in lieu of the Babcock and Wilcox boiler originally provided for. By this alteration the heating power will be slightly increased, and a water-softening apparatus will be unnecessary, which will effect a reduction of £440 in the outlay. It is also thought probable that two sets of storage batteries, instead of four, will be sufficient for present requirements; and it is, therefore, proposed that power shall be reserved to take two sets only, and for the consequent reduction of the contract sum. After setting out the tenders received the report continues:—

The Committee recommend that contracts be entered into as follows; and that, in consequence of the delay since the tenders were received, the time for the completion of the works be extended three months beyond the dates mentioned in the specification, namely:—

For Section A—	
With Mr. John T. Chappell, of 149, Lupus-street, Pimlico, S.W., to erect the buildings for the generating station in accordance with the amended plans	£3,989
For Section B—	
With Messrs. Yates and Thom (W. and J. Yates), of Blackburn, for supplying and setting three Lancashire boilers ...	2,294
For Section C—	
With Messrs. Sharp and Kent, of 34, Victoria-street, S.W., for supplying and fixing four sets of steam dynamos, pumps (piston speed 50ft. per minute), an overhead traveller, and certain instruments, apparatus, and appliances, including six weeks' running of the dynamos. (The dynamos are to be of the Goolden type)	7,027
For Section D—	
With the Electrical Construction Corporation, Limited (formerly known as the E.P.S. Company), Worcester House, Walbrook, E.C., for the supplying and fixing of four sets of storage batteries with stands, switch boards, instruments, and appliances	5,242
[A right to be reserved under the contract for the Corporation to take two sets only of the batteries, the contract price being reduced to £2,700, and the balance of £2,542 being paid if and when the remainder of the batteries are required.]	
For Section E—	
With Messrs. Sharp and Kent, for supplying, fixing, and connecting certain electrical instruments at the Generating Station, North-road	1,140
For Section F—	
With Callender's Bitumen Telegraph and Waterproof Company (Limited), of 101, Leadenhall-street, E.C., for supplying and fixing electrical cables, leads, and wires..... £9,096 For separate test wires, &c..... 204	9,300
For Section G—	
With Callender's Bitumen Telegraph and Waterproof Company (Limited), for supplying and fixing street and other boxes, instruments, and appliances.....	437
Total.....	£29,429
If the Council should decide to take only two sets of storage batteries there will, in respect of the other two sets, be deducted from this total a sum of	2,542
Leaving the net outlay, exclusive of the cost of site, at ...	£26,887

Bromley.—Messrs. Laing, Wharton, and Down have given notice of their intention to apply for a Provisional Order.

LEGAL INTELLIGENCE.

Bolt v. London Electric Supply Corporation.

In the Westminster County Court on Thursday last week, the case of Bolt v. The London Electric Supply Corporation was before his Honour Judge Bayley.

The action was brought by Messrs. Bolt Brothers and Co., oil merchants, to recover the sum of £42. 12s. 8d. for oils supplied by them to the defendant firm. The oil supplied was of a peculiar character, and was used for the engines driving the electric light machinery at the Grosvenor Gallery. There were now 110 gallons owing for, and they formed the subject of the present claim.

Mr. CLEATON, a member of the plaintiff firm, said that in March last year he had an interview with some of the heads of the defendant firm with reference to making some lubricating experiments on the defendants' engines at the Grosvenor Gallery station. Certain oil was specially prepared for the work, and on March 8th the experiments took place. They did not, however, prove satisfactory, but that was purely owing to the defendants not fitting up a proper oil tank. A number of drums of oil were supplied, containing in all 100 gallons. A portion of the oil had been used, but no part had ever been returned by the defendants.

For the defence, Mr. LYNCH submitted that, according to an agreement entered into between the parties, either side were to terminate the experiments if they were found to be unsatisfactory. Had they gone on for a month as arranged, no doubt the defendant company would have had to pay the plaintiff the agreed sum of £50. The trials, however, were concluded upon the very same day they were commenced; therefore it was contended that the defendants had incurred no liability as the matter had fallen through, but a sum of £2. 9s. 6d. had been paid into Court for the one day's experiment.

His HONOUR said he failed to see how the plaintiff could show that oil supplied, as in the present case, was oil sold and delivered. It was simply an experiment. Judgment would be entered for the defendants, with costs.

TRADE NOTES AND NOTICES.

TENDERS WANTED.—The Goole Local Board invite tenders for lighting the town with gas or otherwise for twelve months from September 1st next. Full particulars may be obtained from Mr. George England, Clerk to the Local Board, to whom tenders must be sent by the 24th inst.

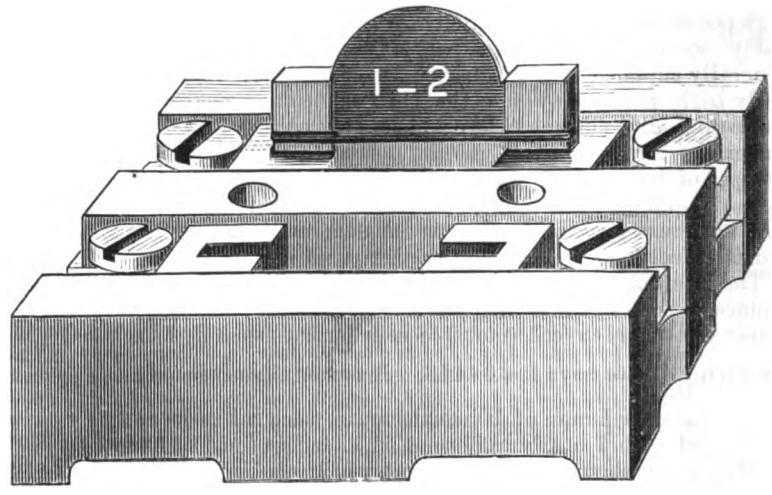
DISSOLUTION OF PARTNERSHIP.—It is announced that the partnership between Messrs. H. F. Price and H. Thompson, trading as the Eclipse Electrical Case and General Cabinet Works at Phœnix-place, Gray's-inn-road, and St. Peter's-street, Islington, has been dissolved.

MESSRS. CATHCART AND PETO.—We are informed that this firm has acquired the business and factory of the Vulcan Manufacturing Company, Rocliffe-street, Islington, London, N. The title of the latter firm will be retained, and Messrs. Cathcart and Peto will continue the business as their Electric Bell department, in addition to their Hatton Garden Works.

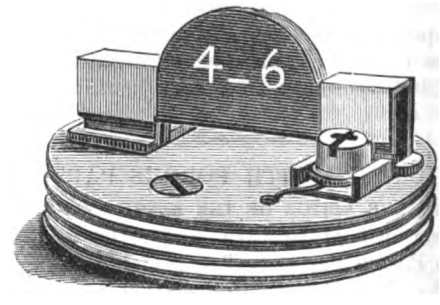
EDWIN FOX AND CO. (IN LIQUIDATION).—We have received from the liquidator the debtor and creditor cash statement respecting the affairs of this firm, which went into liquidation at the end of 1887. The accounts are made up to February 18th, 1890, and were received by us on July 10th. Some £25,000 appear to have been collected, with an exactly equal amount expended, which is a very satisfactory realisation for the creditors, the more particularly as it has only cost £1,211 3s. 8d. to realise, of which sum the liquidator is content with £549 16s. 2d., which from the accounts rendered seems to be about £300 less than might legally have been claimed by him! We were given to understand at the early part of 1888 that the creditors of the Company would receive a considerable dividend out of the estate; but this, we regret to say, is not to be. The liquidator is Mr. John S. Ball, 1, Gresham-buildings, Basinghall-street, London, E.C.

MESSRS. CROGGON AND CO. (LIMITED).—It will be remembered that Messrs. Croggon and Co., in November last, added to their electrical department Messrs. Pressland and Co.'s stock and plant, appointing Mr. W. T. Pressland manager of this department. We have received an illustrated catalogue from the firm, showing a number of artistic electric light fittings, an electric show-board, various qualities of electric bells, electric bell circuit connections, indicators, indicator movements, brass and bronze pulls and pushes, china pushes, wood pushes, switches, galvanometers, contacts, fire alarms, batteries, porous pots, battery jars, tubes, battery boxes, gongs, medical coils, magneto machines, induction coils, terminals, telephone sets, sections of lightning conductors, insulators, galvanised brackets, &c. The catalogue also contains illustrations of speaking tube fittings, and tables and price lists of the firm's high-conductivity electric wires for bell work, telephones, &c.

THE "VERITY PATENT SAFETY CUT-OUT."—In this cut-out (an illustration of which appears below) contacts are placed at a given distance apart for a given quantity of current. The mounted fuse is also of a given length to exactly fit the contacts of the fuse blocks, making it impossible to fix a large fuse into a block where the length between the contacts is intended for a smaller size. A



small fuse can be put into a large block if required, but on being overloaded would at once melt, and, as each block is stamped with a number of amperes, the contact pieces are arranged for; when once the proper size of cut-out is fixed, a fuse of a larger size can by no inadvertency be inserted. The safety blocks are made interchangeable as far as possible, so that the same fixing screws and



holes will do for any size block. This is found convenient, as alterations are often made in house-wiring, and lights added on to branch circuits where the carrying capacity of the branch conductors admits. Mr. J. G. S. Cunnington, the inventor of the cut-out, has made a series of careful tests on fuses, and has found that if a lead or composition fuse be not coated with grease, resin, or a similar compound, it becomes oxidised when heated, going to a white heat, and carrying 50 per cent. more than the current required to melt it when not so coated. As an additional security,

Digitized by Google

therefore, all the fuses supplied with these blocks are treated with a compound of resin, which insures the fuse melting at its normal melting point—612°F. The parts are very well made, and have sufficient metal to insure contact and to avoid the joints heating, while the screw connections are of ample size for the cables.

MESSRS. F. H. ROYCE AND CO.—We have received from Messrs. Royce and Co. their new price list of compound or shunt-wound dynamos, for which the firm claim an exceedingly high efficiency.

POSTAL REFORM.—We regret to say that the announcement in our last issue, that the Postmaster-General had agreed to an alteration in the Book Post Rules, by which open envelopes could be used, was incorrect.

COMPANIES' MEETINGS & REPORTS.

The India Rubber, Gutta Percha, and Telegraph Works Co., Limited.

The half-yearly general meeting of this Company was held yesterday at the Cannon-street Hotel; Mr. S. W. SILVER presiding.

The SECRETARY (Mr. Tyler) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, the object of our meeting is set in the notice just read; and in accordance therewith I move,

"*That an interim dividend of 5 per cent., or 10s. per share, free of income-tax, payable on and after the 11th inst., be now declared.*"

In doing this I may remark that a rough estimate formed of the amount of sales in the past six months will fully justify it, as it is in excess of that of any previous half-year, notwithstanding the severe competition met with and the considerable increase in the price of the raw material. I am glad to be able to inform you that the works are fairly well employed. Under these circumstances we look forward to the pleasure of meeting you at the commencement of another year, when the books of the Company will be made up. I need scarcely remind you that these results have been attained only by the closest attention to the business, together with the co-operation of all employed in making this institution a great success.

The MANAGING DIRECTOR (Mr. Gray) I have much pleasure in seconding the resolution. You are aware that our workpeople at Silvertown were out on strike from the 18th September to the 10th December last year. This did not occasion us much loss, as we could execute our orders from our works in France. The strikers were aided by some lawless ruffians in intimidating and using violence to our respectable workpeople who wished to continue their work. If the police authorities had taken proper measures to prevent this, the extension of the strike would have been prevented and the places of the small number who went out on strike at the beginning would have been filled up by the new men, and the strike would have ended in a week. As it was, the strike continued about 12 weeks, and the loss to the workpeople was about £20,000, which they would have received had they been allowed to remain at work.

The resolution was carried unanimously.

On the motion of Dr. SMALL, seconded by Mr. RUDD, a vote of thanks was passed to the Chairman and Directors; and the proceedings terminated.

Eastern Telegraph Company (Limited).

The following is the report and accounts of the Directors for the half-year ended March 31st, 1890, to be presented to the thirty-sixth half-yearly ordinary general meeting, to be held at Winchester House, E.C., on Thursday, the 17th inst., at one o'clock:—

The revenue for the period amounted to £424,023. 14s. 3d., from which are deducted £98,477. 16s. 3d. for the ordinary expenses and £47,520. 2s. 11d. for expenditure relating to repairs, renewals of cables, &c., during the half-year. After providing £2,943. 10s. 7d. for income-tax, there remains a balance of £275,082. 4s. 6d., to which is added £61,151. 1s. 5d. brought from the preceding half-year, making a total available balance of £336.233. 5s. 11d.

From this amount there have been paid—

Interest on Debentures and Debenture Stock	£28,274	13	1
Dividend on Preference Shares	20,474	3	3
An interim dividend of 1½ per cent. on the ordinary shares	50,000	0	0
	£98,748	16	4

Leaving a balance of £237,484. 9s. 7d., from which £125,000 has been carried to general reserve.

The Directors now recommend the declaration of a final dividend for the year ended March 31, 1890, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 18th inst., free of income-tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent., for the year on the ordinary shares. The balance of £2,484. 9s. 7d. shown at the foot of the revenue account is proposed to be carried forward to the next half-year.

The revenue includes £74,337. 8s. dividend and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

The Convention referred to at the last general meeting between the French Government and this Company, for the renewal of the agreement for the direct line through France, and the landing and working of submarine cables at the Company's station at Marseilles, has since been ratified, and the agreement has been renewed between H.M. Postmaster-General for a special wire by land line and cable connecting this line with London.

A Convention has been entered into with the Italian Government for the prolongation for 20 years of the existing concessions, for the working and maintenance of submarine telegraph cables between Italy, Malta, Corfu, and Egypt.

The Directors have concluded an agreement with the Turkish Government for the laying of a short section of cable between the Island of Perim and Sheikh Seyd, which will bring to this Company's system the traffic from Hodeida, Mocha and other points on the coast of Arabia now being connected by the Turkish Government with their system of land lines to Jeddah.

The International Telegraph Conference has been held in Paris, at which the Chairman, Managing Director, and other representatives of the Company attended. The interests of the Company were carefully watched, and the result has been on the whole not unsatisfactory.

Sundry reductions in the Continental tariffs were made, to come into operation in July, 1891, which will affect the Company's revenue to a moderate extent, but the Directors hope that the increase of traffic will eventually recoup the loss.

Negotiations of an important character are being carried on between the Eastern Extension Company and the Australian Colonies, with a view to effecting a large reduction in the tariff to Australia. This Company is interested in these negotiations in so far as it will take a part of the risk, trusting that the reduction of tariff will tend to a large increase of traffic, and it is believed that these negotiations will speedily be brought to a satisfactory conclusion.

The several sections of the Company's cables are in good working order, with the exception of the original Red Sea cable, which connects Suakim with Suez and the Island of Perim. The frequent interruptions of this cable taken in connection with the prospect of increased traffic to Australia necessitates the laying of an additional cable in the Red Sea from Suez to Aden which the Directors expect to have completed and in working order before the end of this year. The cost of this will be taken mainly from the reserve fund.

The South of England Telephone Company (Limited).

The following is the report of the Directors to be presented to the seventh ordinary general meeting of the shareholders, to be held at Winchester House, E.C., on Friday, the 18th inst., at 12 o'clock:—

The expenditure on capital account for the past year amounts to £14,116. 2s. 10d., bringing the total of that account to £78,418. 2s. The revenue account shows a sum of £21,549. 18s. 9d. for subscriptions and rentals, and a net credit balance of £6,148. 5s. 4d.; making, with the sum of £627. 1s. 2d. brought forward from last year, an available balance of £6,775. 6s. 6d. Of this amount, the sum of £1,796. 14s. 7d. has been absorbed by the payment of an interim dividend on the Preference shares at the rate of 6 per cent. per annum for the half-year ending October 30, 1889. In order to strengthen the position of the Company, the Directors have considered it advisable to carry £1,000 to the reserve fund; and they now recommend the payment of a final dividend at the rate of 6 per cent. on the Preference shares (£2,096. 6s. 2d.) for the half-year ending April 30, 1890, and the payment of a dividend of ½ per cent. on the Ordinary shares, free of income-tax (£1,500) for the year, leaving a balance of £382. 5s. 9d. to be carried forward.

The completed trunk lines are as follows:—Brighton—Shoreham; Brighton—Eastbourne; Brighton—Worthing; Shoreham—Worthing; Brighton—Hurst; Brighton—Newhaven; Brighton—Rottingdean; Brighton—Lewes; Lewes—Eastbourne; Canterbury—Ramsgate; Ramsgate—Margate; Ramsgate—Sandwich; Ramsgate—Deal; Canterbury—Faversham; Canterbury—Whitstable; Canterbury—Dover; Dover—Folkestone; Chatham—Maidstone; Norwich—Great Yarmouth; Northampton—Wellingboro'; Wellingboro'—Kettering; Kettering—Rushden; Tunbridge Wells—Tonbridge.

The trunk lines in process of construction are:—Canterbury—Ashford; Faversham—Sittingbourne.

At the 30th April this year 2,265 exchange lines and 583 private lines were completed, and 91 exchange lines and 19 private lines were in course of construction.

Telephone exchanges are now open at the following places:—

Brighton	Hastings and St. Leonards	Margate	Rushden
Cambridge		Newhaven	Sandgate
Canterbury	Hurst	Northampton	Sandwich
Chatham	Hythe	Norwich	Shoreham
Deal	Ipswich	Oxford	Tunbridge Wells
Dover	Kettering	Peterborough	Watford
Eastbourne	King's Lynn	Ramsgate	Wellingborough
Faversham	Lewes	Reading	Whitstable
Folkestone	Maidstone	Rottingdean	Worthing
Great Yarmouth			

Mr. D. Owen Bateson retires from the Board by rotation, and being eligible offers himself for re-election. The shareholders' auditor, Mr. J. Weise, retires, and is eligible for re-election.

The following comparative statement of exchange and private line business of the Company is issued with the report:—

	Exchange.	Private.
April 30th, 1886	687	248
April 30th, 1887	1,130	348
April 30th, 1888	1,521	386
April 30th, 1889	1,972	500
April 30th, 1890	2,356	602

NEW COMPANIES REGISTERED.

BARRY AND CARDIFF ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—Registered by Fox and Thicknesse, 11, Abchurch-lane, E.C., with a capital of £1,000 in £1 shares. Object, to carry on the business of electrical engineers.

BRISTOL ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by S. Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object, to carry on the business of electrical engineers.

CAMBERWELL AND ISLINGTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Registered by Fox and Thicknesse, 11, Abchurch-lane, E.C., with a capital of £1,000 in £1 shares. Object, to carry on the business of electrical engineers.

CANTERBURY ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object, to carry on business as electrical engineers, &c.

CARDIFF ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by S. Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object, to carry on the business of electrical engineers.

DEVONSHIRE ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—Registered by Fox and Thicknesse, 11, Abchurch-lane, E.C., with a capital of £1,000 in £1 shares. Object, to carry on the business of electrical engineers.

DISTRICT MESSENGER SERVICE AND NEWS COMPANY (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, London, E.C., with a capital of £200,000, in £5 shares, of which 200 are founders' shares. Objects: To manufacture, fit up, let, or sell electrical appliances of all kinds for the transmission, communication, or making in any way of messages and signals, or to serve as alarms, watch signals or indicators, and to engage and procure messengers and watchers, adopting therefor an agreement made with Charles Tweed Russell, of 18, Southwell-gardens, South Kensington, the particulars of which are not specified in the Articles of Association.

EAST COAST ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—Registered by Fox and Thicknesse, 11, Abchurch-lane, E.C., with a capital of £1,000 in £1 shares. Object, to carry on the business of electrical engineers.

S. Z. DE FERRANTI (LIMITED).—Objects: To carry on the business of electrical engineers and contractors for the supply of electric power. Capital, £100,000, in £10 shares. Subscribers of one share each are: S. Z. de Ferranti, engineer, Charterhouse-square, London; Francis Ince, solicitor, St. Benet-chambers, Fenchurch-street; C. P. Sparks, engineer, Charterhouse-square; Fred. W. Hunter, accountant, 2, Dunwood-road, Stroud Green; Arthur Wright, electrician, Preston Park, Brighton; H. W. Kolle, engineer, Egremont, Tulse Hill; and Edward B. Ince, solicitor, St. Benet-chambers, Fenchurch-street. Vote per share. First Directors (two to five), S. Z. de Ferranti, Francis Ince, and Charles Pratt Sparks, and their appointees. Qualification, 100 shares. Remuneration to be fixed by the Board with consent of general meeting. Borrowing limit not specified. Registered, June 26th, by Gerard B. Ince, solicitor, St. Benet-chambers, Fenchurch-street, London.

HANLEY (STAFFORDSHIRE) ELECTRICITY SUPPLY COMPANY.—Registered by S. Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object, to carry on the business of electrical engineers.

INDIA RUBBER ESTATES COMPANY (LIMITED).—This Company was registered on the 2nd inst., with a capital of £235,000 in £1 shares, to cultivate the india-rubber and other gum-producing trees and plants, and to utilise the produce thereof. The Company will enter into an agreement with Mr. Otto Hienemann. The number of Directors is not to be less than 3, nor more than 9; qualification, £250 in shares. The subscribers are to appoint the first. Remuneration, £2,000 per annum, divisible. and in addition £100 to each Director for every £5 per cent. per annum dividend beyond £15 per cent. Solicitors, Messrs. Gordon, Ross and Douglas Norman, 8, Draper's-gardens.

IPSWICH ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by S. Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object, to carry on the business of electrical engineers.

CITY NOTES, &c.

ALLGEMEINE ELECTRICITATS GESELLSCHAFT, BERLIN.—This Company is about to increase its capital by 3,000,000 marks. The new shares will be offered at 55 per cent. premium.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended July 4th amounted to £4,481, as compared with £4,068 for the corresponding period last year.

DIRECT SPANISH TELEGRAPH COMPANY.—The receipts of this Company for the month of June show an increase of £485 as compared with the corresponding period.

EASTERN TELEGRAPH COMPANY.—Notice is given that the register of transfers of this Company will be closed from the 10th to the 17th July, both days inclusive.—The traffic receipts of this Company for the month of June amounted to £51,019, as against £44,805 for the corresponding period of 1889, or an increase of £6,214.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic returns of this Company for the month of June are £43,198, as against £39,350 for the same period last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company are as follows:—Receipts in June, 1890, £24,600; January 1 to June 30, 1890, £130,400. Corresponding months in 1889, £129,400; ditto in 1888. £132,000.

INDIA RUBBER ESTATES COMPANY (LIMITED).—This is the title of a new Company issued this week with a capital of £225,000 in £1 shares, the list of subscribers for which closed yesterday. The Company is formed to work a concession from the Government of Siberia for collecting and exporting india-rubber and gutta-percha for the European and American market, and for the purpose of acquiring and working other concessions relating to india-rubber and gutta-percha from other foreign Governments in Africa, America, Madagascar, &c.

MONTEVIDEAN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The offices of this Company have been removed from 2, Tokenhouse-buildings, to Langthorne House, Copthall-avenue, London, E.C.

STOCK EXCHANGE.—The Committee have appointed to-day (Friday) the settling day in the Morgan Crucible Company (Limited), Preference Shares, Nos. 1, to 20,000; and have ordered these securities and the Commercial Cable Company's $7,216,000 capital stock to be quoted in the official list.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED). Notice is given that the transfer books of this Company will be closed from the 7th to the 15th inst., both days inclusive, preparatory to the payment of an *ad interim* dividend of 12s. per share to all shareholders on the register on the 7th inst.

WEST END STREET RAILWAY COMPANY OF BOSTON.—This Company, now working a large percentage of its entire equipment by electricity, has declared a semi-annual dividend of 4 per cent. on the Preferred, and of 5 per cent. on the common stock of record June 14th, payable July 1st.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended July 4, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,451.

COMMERCIAL AND INDUSTRIAL FINANCE.—On Wednesday, July 2nd, the *Financial News* dealt with the subject of the profits of joint-stock companies, showing in a carefully-compiled table the appreciation in the value of shares in a number of commercial and industrial concerns, including many electrical companies. On Monday last our contemporary returned to the subject, and showed in another interesting table the dividends paid by the various companies since their formation into limited liability companies. So much has been written on the seamy side of the question that we think it only right to show that so far as electrical companies are concerned there are two sides to the matter; and the following extracts from these tables will no doubt be interesting to our readers. It will be seen that the total dividends paid amounts to no less than £16,075,420, while the appreciation in value of the shares is £26,813,718. Our contemporary promises some further figures later on, which, we have no doubt, will be of equal interest with those previously given:—

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 635.—Vol. XXV. FRIDAY, JULY 18, 1890. Price Fourpence.

NOTES.

The first Paper read at the Edinburgh meeting of the Institution of Electrical Engineers on Tuesday last was essentially of a practical character, inasmuch as it enabled the members to make the best possible use of the short time at their disposal by directing their attention to that which was really deserving of notice. In reading his Paper "On Some of the Chief Features of the Exhibition, and mainly of the Electrical Section," the author, Dr. Walmsley, acted the part of scientific showman; and if the office which he thus performed was not characterised by that originality which scientific authors are usually supposed to aim at, it was at least very useful. It is strange that papers of this kind are not more often forthcoming. Last year, when the Institution met at Paris, some members suggested that a French scientist should be asked to read a Paper descriptive of the more important electrical exhibits, but the Council did not think it expedient to accede to this proposal, being apprehensive that the advertising element might be uppermost in such a Paper, and interfere with the scientific dignity and impartiality of the Institute. The consequence was that we had no such Paper, and members had to find out the best way they could what was, and what was not worth inspecting. This, of course, means considerable waste of time and vital energy. To look through exhibitions entails physical and mental exertion, and the more we can reduce the exertion the greater will be the ultimate gain to be derived from the inspection of really important objects.

As a practical guide to the Exhibition, Dr. Walmsley's Paper was all that could be desired. It dealt first with the exhibits of historical interest, and then went on to describe those representing machinery and apparatus in use at the present time. Telegraph-engineers will be interested to learn that amongst the historical exhibits shown by the Post Office is one which identifies Charles Morrison with the first electric telegraph. The first proposal for such a telegraph was published in the *Scots Magazine* of 1st February, 1753, over the initials "C. M.," and according to this proposal the telegraph would consist of 24 insulated wires erected between the points to be put in communication, one wire for each letter of the alphabet, and words would be spelled out by electrifying the wires from one end in succession. At the other end of the line particles of paper or straw would be attracted also in succession, and thus messages received. Whether a telegraph has ever been constructed on this principle seems doubtful, and it is equally doubtful whether, even if Morrison's idea had been brought into practical form, we should call him the father of the electric telegraph. It is one thing to vaguely indicate certain scientific possibilities, and quite another thing to carry out practically a new idea. This Morrison certainly never did.

Whilst describing Sir William Thomson's syphon recorder, Dr. Walmsley made incidentally a remark which will be endorsed by all English electricians. He drew attention to the fact that the D'Arsonval galvanometer, about which we have heard so much during the last few years, is nothing else but a revival of the corresponding part in the syphon recorder, and that it therefore should properly be called the Thomson galvanometer. The wonder is that the similarity between the two instruments has not been pointed out before. The arrangement of a coil suspended between fixed poles and an inner soft-iron fixed armature is, as Dr. Walmsley points out, to be found in Maxwell.

The information given as regards the extent to which the Delany Multiple Telegraph is in use in this country had to be corrected by Mr. Preece. Instead of there being only two lines worked by this system, it turned out that there are some 15 or 16. This is a fair list of applications for an instrument which was rather neglected in the country of its birth, and only brought to light by the official recognition it received from our own telegraphic authorities, who, in this case, were certainly not behind-hand in recognising the value of an invention made "outside of the department."

On the subject of dynamo-electric machines Dr. Walmsley had a good deal of interesting information to lay before the meeting. Of historic interest is the first magneto-electric machine built in 1844. This machine was also shown last year at Birmingham, and was pretty fully described in these columns in our issue of October 4, 1889. The armature has eight coils, and the field is composed of four permanent horseshoe magnets, each provided with a keeper of soft iron, which can be fixed at any point along the limbs, thereby more or less short-circuiting the flux of magnetic lines. This provision was adopted to regulate the electromotive force, so as to suit any kind of depositing work for which the machine might be required. Of modern machines, those designed for

Digitized by Google

ship lighting are naturally well represented in an exhibition held in a district so important for marine work generally. On board ship compactness of plant is one of the primary considerations, and in this connection it is interesting to compare the different exhibits as regards the relation between floor space occupied by the combined engine and dynamo, and the output of the latter. This has been done by Dr. WALMSLEY, and we give below his table in an abbreviated form.

Exhibitors.	Output in kilowatts.	Revolutions per min.	Steam pressure lbs. per sq. in.	Floor space occupied.	Watts per sq. ft. of floor space.
King, Brown	44	300	120	8′ 6″ × 3′ 0″	1,725
,, ,, ...	12·6	285	160	5′ 6″ × 2′ 9″	834
Ernest Scott	4·8	380	80	6′ 0″ × 3′ 0″	267
Brush Company...	6·5	300	80	6′ 0″ × 2′ 8″	406
Silvertown	36 7	300	100	8′10″ × 4′ 3″	872
Napier Prentice...	11	550	100	— —	355

As regards the last-mentioned firm, their dynamos have only recently been put on the market. The peculiar feature is the armature, which is a Pacinotti Drum closed with metal covers at the ends, so that no wire is visible. The grooves between the teeth are covered with strips of bone, and the firm claim that these armatures are completely waterproof. On this point we must defer an opinion until a test by some independent authority has been made; but, judging from appearance, we should not be surprised to find that the claim of the designer will be realised in actual practice.

MR. RAIKES' influence at the Treasury must be very powerful to extract from that Department concessions to the telegraphists costing nearly a quarter of a million per annum, especially when a still more expensive revision is impending under the same auspices for the benefit of the postmen. It is, perhaps, too much to hope that the men will be satisfied; but they can hardly fail to be surprised at the liberality with which their demands have been met. Besides considerable extensions of the scale maximum of each class, a rate and a-quarter is to be paid for overtime, whilst duty on Sundays and Bank Holidays is to be paid for as overtime—a privilege which until now only the metropolitan clerks enjoyed. For all alike full pay will be allowed during sickness. Short of an abolition of the classes, which Mr. RAIKES very properly would not consent to, the telegraphists could hope for nothing better, and probably expected something less. It is satisfactory to notice that the female staff participate in these boons, although they have taken little or no part in the unseemly agitation which lately has discredited a certain section of the male staff.

PROBABLY the leading agitators will say that all this has been extorted under pressure of their organised terrorism. That is a matter of opinion—the truth perhaps is that all it has done has been to quicken the movements of the departmental Committee. But be that as it may, the exclusion of the more violent spirits to the number of nearly 200 from the benefits of this revision will have the effect of demonstrating that leadership of threatening movements like these in the public service is attended with no small risk. It is only to be regretted that the responsible ringleaders, like Mr. MAHON, will not get their deserts.

THE announcement that the Committee of the House of Lords has put its veto upon the Central London Railway Bill will, we think, be received, as the *Standard* expresses it, with "indignant surprise." The Bill was discussed for thirteen days before a Select Committee of the Lower House, and the conclusion then arrived at was, that the proposed railway was likely to prove a public benefit, and ought to be allowed. Such also was the general opinion of the House of Commons itself, if we may judge by the brief debate which preceded the third reading of the Bill. But the spectacle of the dome of St. Paul's emulating the Leaning Tower of Pisa, and of Oxford-street transformed into a grass-grown thoroughfare, which was conjured up by opponents of the scheme, seems to have carried great weight with the House of Lords' Committee; for, after deliberating for fifteen minutes upon the evidence, they decided that the preamble was not proved. It is, however, impossible to find fault with the reasons upon which this remarkable decision was based, for none were given.

THE electric lighting scare which was created in this country in the early part of the present year by the fatal accidents in New York, and the discussion of the *pros* and *cons* of execution by electricity, gave rise, as many of our readers will remember, to several questions in the House of Commons; and in April Sir MICHAEL HICKS-BEACH promised to obtain some reliable information as to the number of deaths in the United States due to the electric current. The American census office was not, however, in possession of the necessary data, and all that the Board of Trade has been able to secure are the results of some investigations which have been made by the municipal authorities of New York. From these it appears that from January 1, 1887, to May 15, 1890, there were only 16 deaths from electricity in New York City, and of this number no less than nine occurred amongst linemen or other electric light *employés*. Considering the manner in which so large a proportion of the electrical work in the "Empire City" has been carried out, an average of about five deaths per annum seems to us a very small one upon which to have started so great a panic.

M. HESS, in *La Lumière Electrique*, usefully calls attention to certain considerations in the design of resistances for strong currents. His remarks are opportune in view of the recent work which has been done on the heating effect of currents, and also in connection with the production of new materials of high specific resistance. In making coils for resistance tests the choice of a material having a low temperature coefficient is very important; but this is not usually the case with coils intended to stand strong currents, nor indeed is high specific resistance a desirable thing. M. HESS shows that if two coils of equal resistance are designed to stand the same current without rising above a given temperature, the coil of higher specific resistance is shorter, while the diameter and volume of

Digitized by Google

the conductor are greater; the ratio in all three cases being the cube root of the ratio of the specific resistances. Thus, if the second coil has 27 times the specific resistance of the first, its length is one third that of the first, while the diameter of, and the volume occupied by, the wire are each three times as great. Unless, therefore, the second material costs only one-third that of the first, it is cheaper to construct the coil of the better conducting substance. This result is not very new, as Mr. W. H. SNELL discussed the question from the same standpoint, and arrived at similar conclusions in *The Electrician* of January 31, 1885. The fact is, however, likely to be overlooked, and is one which tends to discourage the search for new materials of very high specific resistance. Unless such substances are cheaper than the old ones they can be used with advantage in but few instances, even if their electrical behaviour is perfectly reliable.

THE LANE FOX negotiations have come to a dead-lock. The Company, which was formed, with a capital of £100, to collect royalties, has now realised that there is no hope of a simple recognition of the patents, and they are not prepared to make a test case. We are informed that they have, therefore, reversed their policy, and propose to let their property and its control go to the highest bidder.

IN another column will be found the judgment of the Scotch Court of Appeal in the compound-winding case, from which it will be seen that Lord TRAYNER'S decision, invalidating the Brush patent, has been upheld. We propose to deal with this important judgment at greater length next week.

Aberdeen.—The Aberdeen Electric Lighting Bill has been withdrawn.

Dorchester.—An electric lighting company has announced its intention of applying for a Provisional Order.

Perth.—The Scottish House-to-House Electricity Company have given notice that they intend to apply for a Provisional Order.

Litherland.—The local House-to-House Company has informed the Local Board of its intention to apply for a Provisional Order.

Penzance.—At the last meeting of the Town Council the Penzance Electricity Supply Company announced their intention of applying for a Provisional Order.

Newry.—The Town Commissioners have decided not to give their consent to the proposed Provisional Order of the Irish House-to-House Electric Lighting Company.

Telegraphic Communication with Bermuda.—The Post Office authorities notify that telegraph communication with Bermuda is established. The charge is 4s. per word.

Personal.—Herr Wilhelm Lahmeyer has severed his connection with the Deutsche Elektricitäts Werke at Aachen, in order to devote more time to experimental research.

Woolwich.—The London Electric Supply Corporation and the Woolwich District Electric Light Company have announced their intention of applying for Provisional Orders.

St. Moritz-Bad.—The large hotels are having a 4,000 light central station built for the 1891 season. The power will be derived from the Julierback in Silvaplana, where it has a fall of 35 meters.

Bridlington Quay.—The temporary lighting of the Parade, which has been undertaken by the Laing, Wharton, and Down Construction Syndicate, was successfully inaugurated on Saturday evening last.

Pembroke.—At the last meeting of the Board of Commissioners of this township, a letter was read from the Electric Lighting Company of Ireland, announcing their intention of applying for a Provisional Order.

King's College, London.—At a meeting of the Council of King's College, London, on Friday last, Mr. David S. Capper, M.A., Assoc.M.Inst.C.E., was elected to the Professorship of mechanical engineering at the college.

Dusseldorf.—A company has been formed by some energetic manufacturers, with the object of building tramways to connect the suburbs, Grafenberg, Derendorf, Rerth, &c., with the town. Electricity will be used as motive-power.

Keighley.—The Town Council has decided to oppose the applications of the Yorkshire House-to-House Electricity Company and the Electric Installation and Maintenance Company for powers to supply electricity within the borough.

Winchester.—At the last meeting of the Town Council, the General Purposes Committee reported that, in accordance with the resolution of the Council, they had invited proposals for lighting the city and municipal buildings by electricity.

Incandescent Lamp Manufacture.—Messrs. Fritsche and Pischon have built an incandescent lamp factory at Fürstenwalde, near Berlin, which is now nearly complete. A distinguishing feature will be a special type of air pump made by the firm.

Whitechapel Board of Guardians.—Notices have been received by this Board from the Laing, Wharton, and Down Construction Syndicate, the London Electric Light Supply Corporation, and the House-to-House Electric Light Supply Company, of their intention to apply for Provisional Orders.

The Electric Sugar Frauds.—Judgment was given on Wednesday in the New York Courts in favour of the English stockholders in the Electric Sugar Refining Company, who sought to recover some of their money by suing Messrs. Cotteril and Robertson, the president and treasurer of the Company.

Perpignan.—The civil tribunal at Perpignan has just condemned M. Bartissol, who has undertaken the electric lighting of the town, to pay 150,000 francs as compensation to a M. Campana for the damage done to his house by the noise, smoke, and vibration due to the proximity of the central lighting.

Leamington.—At the last meeting of the Town Council notices of intention to apply for powers to supply electric light in the borough were received from the Municipal and Electric Lighting Power Company, the Electric Installation and Maintenance Company, and the Midland Electric Light and Power Company.

Stretford.—At the last meeting of the Local Board, the sub-Committee, who have had charge of the question of electric lighting, said that the terms of a Provisional Order had been arranged with the Yorkshire House to-House Electricity Company, and recommended that the Order should receive the approval of the Board. The motion was adopted.

Berlin.—The arc lamps along the Unter den Linden have hitherto been connected 12 in series, and supplied by special machines in the Centrale Manerstrasse, giving 600 volts. As soon as the cables for the private supply of current in the above named street are laid and at work, the lamps are to be connected two in series across the ordinary mains.

University College, Bristol.—The autumn session begins on October 1st. The electrical engineering department, under Prof. J. Ryan, includes lectures and laboratory work, in a course covering three sessions. The chemical department, under Prof. Sydney Young, offers both daily and evening lectures. Further information will be found in our advertisement columns.

Dewsbury.—At the last meeting of the Town Council, the Gas and Water Committee reported that a letter had been received from an electric lighting company, giving notice of

Digitized by Google

intention to apply for a Provisional Order. The Town Clerk reported that he had had an interview with the solicitor to the Company, and had informed him that the Corporation of Dewsbury intended making application, and would therefore oppose the Company's request.

Incandescent Lamps in the Colonies.—We draw the attention of our readers to the notice given by the Brush Electrical Engineering Company in our advertisement columns as to the use of incandescent lamps in Australasia, India, Natal, and the Cape. It appears that, having acquired the Edison lamp patents, the Company regard it as an infringement of the rights which they have secured, to import, sell, manufacture, or use *any* incandescent electric lamps in those territories.

Bath.—The difficulties in the electric lighting of this city appear to be nothing more serious than defects which occurred in the arrangement for raising and lowering the lamps. This has now been altered, and steps are being taken to fix the lamps and run the current direct to them without going through an intermediate switch, the constant removal of the lamps having allowed the water to enter. The lowering of the lamps by means of a cord was adopted in order to avoid the constant use of ladders.

The Interruption of the Australian Cables.—On the night of the 10th instant the three cables of the Eastern Extension, Australasia, and China Telegraph Company, between Banjoewangie (Java) and Australia, were simultaneously interrupted by an earthquake, the shock of which was felt an hour before on shore. Telegraphic communication with Australia, which was thus entirely cut off, is expected to be restored within a day or two, the ship being on the spot and momentarily expected to communicate on one of the severed cables.

The Electric Light in Night Attacks.—Sir Evelyn Wood, in his report on the night operations of the 10th inst., says:—"The night was dark and rain was falling when the general with the officer in charge arrived at the observation station of the electric light. The position was not favourable for observation. . . It was impossible to make out the nature of the bodies which were on the road. The light, however, was of great assistance to the picquets, enabling them to see along the flat road quite a mile in front of them."

Electric Lighting Orders.—In the House of Lords, on Tuesday last, Lord Balfour of Burleigh moved:—"That the Sessional Order of March 10th last, 'That no Bill brought from the House of Commons confirming any Provisional Order or Provisional Certificate shall be read a second time after Friday, June 27th next,' be dispensed with in respect of Bills to confirm Provisional Orders made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, and brought from the House of Commons on or before the 28th inst." The motion was agreed to.

Southampton.—Notices of intention to apply for Provisional Orders have been served on the Corporation by the Southampton Electric Light and Power Company; the National Electric Supply Company; the Electric Installation and Maintenance Company; and the South of England House-to-House Electricity Company. At the last meeting of the Town Council, the Lighting Committee recommended that the Southampton Electric Light and Power Company should be offered the sum of £750 for the transfer of the licence which they hold. After a lengthy discussion it was decided to refer the matter to a Committee of the whole Council.

Steno-Telegraphy.—The system of steno-telegraphy, which we fully described in our issue of the 4th inst., was tried on Thursday last week at the Palais Bourbon, in the presence of M. Floquet and the Secretaries of the Chamber. The wire on which the experiments were carried out had a length of about two miles and a half. M. Cassagnes stated that he had transmitted reports at the rate of 25,000 words an hour from Paris to Brussels; of 18,000 an hour to Lyons; and of 15,000 an hour to Marseilles. By means of his manifold system, M. Cassagnes claims to be able to supply simultaneously, with one instrument, all the papers of Paris with Parliamentary reports.

Electric Lighting Notices in the Metropolis.—At the last meeting of the London County Council, the Highways Committee informed the Council that notices of intended applications for Provisional Orders had been received from the St. James's and Pall-mall Electric Lighting Company for the parishes of St. James's, Westminster, and St. George's, Hanover-square; from the Westminster Electric Supply Corporation for the parishes of Paddington, Chelsea, St. Marylebone, Kensington, and part of St. Margaret and St. John, Westminster; and from the New Cadogan and Belgrave Electric Supply Company for the parishes of St. George's, Hanover-square, and Chelsea.

Obituary.—The death recently took place of Mr. Alexander Parkes, of Rosendale-road, West Dulwich. Mr. Parkes found his way at an early age to Messrs. Elkington's, where he devoted a large amount of attention to the details of the then newly-discovered process of electro-deposition. In 1840 improvements suggested by Mr. Parkes were combined in Messrs. Elkington's patent with the famous discovery of Mr. John Wright, who, by the use of cyanides of potassium, succeeded in producing firm and thick deposits of silver and gold by electro-deposition—then the great desideratum of the electro-plating process. His investigations were also directed very largely to the subject of the refining of copper. Mr. Parkes ultimately severed his connection with the firm, and received a large sum in recognition of the services which he had rendered. The invention of Mr. Parkes, which is of the most popular interest, is that of a substance which is now largely known under the name of celluloid or zylonite, but which was originally known as Parkesine.

A Central Station Struck by Lightning.—With regard to the central station of the Manhattan Electric Light Company, which, as we announced in our issue of June 13th, was struck by lightning, later information shows that the lightning did not strike one of the company's circuits and come into the building over the wires, but that it struck the roof of the building itself, and started a fire, which did the damage. The station supplies 20,000 incandescents and a large number of arcs. The damage done was confined to the dynamo room and the offices and store rooms. Out of about 30 machines only two or three escaped serious injury. The incandescent circuit switchboard was entirely destroyed. The arc-light switchboard was partially consumed. Every belt in the station was so badly burned as to require an entirely new outfit. The work of reconstruction was begun at once after the fire. The night after the fire about one-half of the arc lights and 12,000 incandescents were supplied with current as usual, while on the second night 17,000 incandescents were connected, and on the third night not far from 20,000 lights. The Company was able to make this fine showing, says the *Electrical World*, through the kind assistance of its very obliging business rivals.

Barnsley.—The Park and Lighting Committee of the Town Council have issued their second report on the subject of electric lighting. The question has been before the Town Council since September last. In November last the committee invited tenders, and received nine estimates from electric lighting companies to put down an installation in the inner area of the borough. The contractors were as follows:—The Gülcher (New) Electric Light and Power Company, £25,500; Electric Construction Corporation, Tender A, £22,751; ditto, Tender B, £21,721; Manchester Edison-Swan Company, £19,200; Westinghouse Electric Company, £17,800; Laing, Wharton and Down Construction Syndicate, £16,975; Electric Construction Corporation, Tender C, £15,108; Brush Electrical Engineering Company, £13,100; National Electric Supply Company, £11,888. The services of Mr. Bromley Holmes were secured to advise the committee. Mr. Holmes reported on June 7, and he further presented a detailed report on the Westinghouse Company's tender, recommending its acceptance. The report was discussed at a meeting of the Town Council on Tuesday, which adjourned, after three hours' discussion, for a fortnight. There was a strong feeling in favour of the adoption of the electric light, provided the price could be reduced

A Messenger Call System for London.—A *conversazione* was given on Saturday evening last by the Boy Messengers

Digitized by Google

Company at the Royal Institute of Painters in Water Colours, for the purpose of exhibiting in miniature the system of messenger calls which that Company is seeking to introduce into the metropolis. Signalling apparatus, provided with suitably marked dials, will be installed for a nominal rental in clubs, hotels, theatres, shops, warehouses and other places of business, and will be in connection with the nearest messenger depôt. The instruments are arranged in series, as many as 100 being placed on one line if necessary. The closed circuit system is employed and the signals from the transmitters are received at the depôt by a Morse embosser. The movement of any one of the levers, which are arranged under the dials of the transmitters, actuates a series of ratchet wheels, causing them to rotate and bring the appropriate wheel into contact with a pawl, the movements of which make and break the circuit. As the ratchet wheels are each differently indented, the result is that the requisite Morse signals are transmitted to the receiving station. To ascertain whether a signal is already on the line, it is only necessary to press a push-button. This throws an electro-magnet into circuit, and if a signal is being sent from any other transmitter of the series the tapping of the armature of the magnet will announce the fact. The present system was originally introduced into this country by Captain Davies, of the Exchange Telegraph Company, and it is needless to say that something similar has been for years in successful operation in New York.

The Rise in Platinum.—Dr. Day, chief of the Geological Bureau, of the United States, attributes the great increase in the value of platinum chiefly to the increased cost of its production at the mines, there being no reason to suppose that the natural deposits are giving out. Hitherto the placers of Nishnee-Taglisk and Goro-Blagodat, in the Ural Mountains, have been richly productive of gold, and the owners of the mines could afford to sell the platinum incidentally obtained for a very moderate price. But now the gold has become scarce, and they are forced to depend to a greater extent upon the platinum for their profits. Of that metal, happily, there is plenty left. Thus it is seen why platinum has doubled in value within a twelvemonth, and is still rising, with no prospect of going down again. A great number of labourers have been drawn from the mines to build the trans-Siberian railway. This, for a time, lessens the production of platinum. At present the large dealers are buying up all the old platinum they can lay their hands on, in anticipation of a future rise in prices, so that a "corner" seems to be arriving in the commodity. This increase in the cost of platinum is of greater importance when it is considered how greatly the use of this metal has increased of late. It will probably never again be half so cheap as it was a year ago. In view of the scarcity of platinum, the Paper by Dr. Wahl, an abstract of which is concluded in another column, will be read with interest. The subject becomes of considerable commercial importance, since, for many purposes, a well-plated article should be as serviceable as one made entirely of platinum.

Attack on a Cable Station.—The following extract from a letter recently received from an officer of the West African Telegraph Company will, we think, interest many of our readers, and especially those who are unacquainted with the difficulties and dangers under which telegraphic work has frequently to be carried on in these out-of-the-way cable stations:—

Kotonou Station, May 1st, 1890.

. . . Our friend the King of Dahomey is, I am glad to say, about to receive a well-merited lesson. Last year, when I was in London, and told you something about the little games of these gentry, I thought the day could not be far distant when all that they had inflicted on us and the rest of the world would be repaid with interest. Last December I asked the Company to supply us with arms, as the blood of "Messieurs les Dahomiens" was visibly warming, a phenomenon by no means surprising, considering our proximity to the sun. But what gives me particular pleasure to relate is that His Majesty Bedazin "Osu Bowélé," which, being interpreted, means "King Shark," who swore he would paddle his own canoe in our blood, failed to keep his word; and I have no hesitation in saying that I prefer working for the W. A. T. to serving as a burnt offering to my friend Bedazin. We had *our* turn on the 4th March. The station was surrounded by the natives, and we were under the painful necessity of sending a few of them across the Styx. Seriously speaking, however, the station was for a time in imminent danger; Orsini and I fired more than 250 rounds each, and the 35 Senegalese sharpshooters who helped in the defence, fired some 120 rounds apiece. An artillery sergeant, who worked our two guns, was killed, and the white gunners were so hard pressed that they had to club their rifles. This racket began at 4 in the morning. At 9 a.m. we left the soldiers still firing, and went to the instruments, and you may imagine what a dance the mirror led us. By 10 o'clock, however, all was quiet in our neighbourhood, and the messages had all been sent through . . . I must not forget to tell you that we had to do with the famous Amazons. They were very fine creatures, fought like wild beasts, and were worth ten men.

Electricity in Mines.—The following are some particulars relating to an electric haulage plant installed at the Erie Colliery of the Hillside Coal Company, at Scranton. The power plant consists of a 60 horse-power Armington and Sims engine, and a 50 horse-power Thomson-Houston dynamo, wound for a current of 220 volts potential. The engine and dynamo room are at the top of the shaft. From the dynamo to the foot of the shaft the current is conducted by wires, enclosed in gas pipes to protect them from damage. From the bottom of the shaft the wires are carried overhead about 12in. outside of the low rail of each track, and are suspended from an insulator specially designed for this class of work. Wherever turnouts occur frogs are used, the conductors being soldered to them in the same manner as when used for street railway work. Connections from the mains to the overhead conductor are made at suitable intervals, and a portion of the current is utilised for lighting purposes, two 110-volt lamps being placed in series. The rails are used as conductors for the return current. The locomotive is of the following dimensions:—Length over all, 9ft. 7in.; width, 5ft. 3in.; and height, 5ft. 6in. This last dimension can be considerably reduced by placing the rheostat at one end instead of on the top, as has been done in the present instance. The weight of the locomotive is 10,500lb., to which 1,800lb. has been added to increase traction. The motor employed is of 40 horse-power. During a period of 11½ days the average number of cars delivered at the shaft bottom by the locomotive was 559·5, against 526·95 per day delivered by mule haulage. To deliver 700 cars per day of 10 hours, the time of running the locomotive would be 5 hours and 30 minutes, leaving 4 hours and 30 minutes for contingencies. The total distance run would be 21·28 miles, and the locomotive would be reversed 232 times.

The Pay of Telegraph Clerks.—The revised regulations relating to the Postal Telegraph Clerks have just been issued by the Postmaster-General to date from 11th inst. The service of provincial sorting clerks and telegraphists is divided into four groups. The first group contains six towns of the first importance, in which collectively 2,186 men and 753 women are employed. It is now decided to raise the scale of pay here for men, from 40s. per week, with annual rise of 2s. to 50s., to a *maximum* of 56s. in the first class, and from a *minimum* of 12s., with rise to 38s., to a *maximum* of 40s. in the second class. For women in this group the existing pay in the first class is 27s., with annual rise of 1s. 6d. to 32s. This will be altered to 28s., with rise to 35s., while in the second class a rise of 2s. on the present maximum is accorded. In the second group, comprising five offices, where 765 men and 172 women are employed, the maximum is raised from 50s. to 54s. in the first class, and from 38s. to 40s. in the second class, for men, while the rise is from 32s. to 34s., and from 26s. to 28s, in the first and second classes for women. In group 3, comprising eight offices, 824 men and 102 women are employed, who in both classes receive an increase, the men of 2s. and the women of 1s. to their present maximum rate of pay. Group 4 comprises 26 offices, in which 1,618 men and 177 women are employed. In the first class of this group the maximum is not raised, though in the second class it is raised by 2s. for both men and women. Of the London male telegraphists—to the first class, who are now on a scale rising to £140, an increased maximum of £20 has been accorded, while the top pay of the second class is raised from £100 to £110; while the female telegraphists have been granted a rise in similar conditions of 4s. per week in the first class and 3s. in the second class. In addition to this, further advantages have been accorded to the staff throughout the country in the matter of overtime, Sunday work, Bank Holiday work, pay for which will be allowed in the provinces as well as in London. Pay during sickness is accorded to all alike. All overtime is to be paid for at a rate and a quarter.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

(Continued from page 261.)

§ 4. **Ganz Transformers.**—Proceeding next to the transformers, we may mention, in passing, the old life-buoy shaped transformer of Zipernowsky merely to point out that it is no longer used in practice. In that early form the primary and secondary coils were wound in circular coils, then laid together, and wound over with iron wire so that the whole arrangement

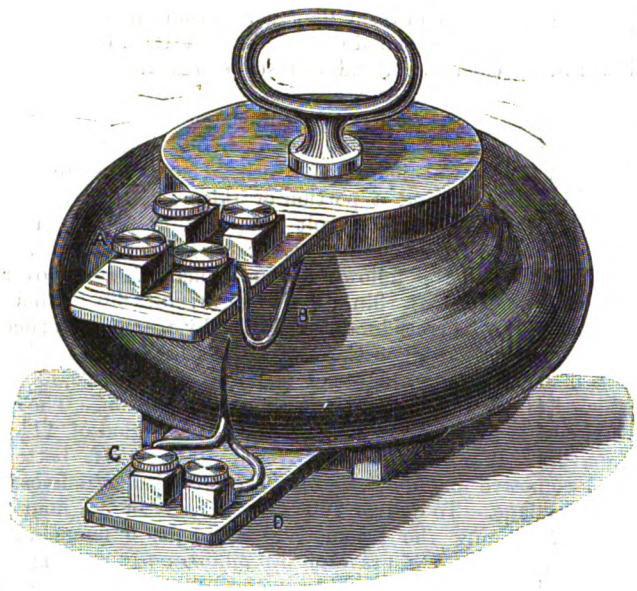

FIG. 8.—Old Form Zipernowski Transformer (1885) not now used.

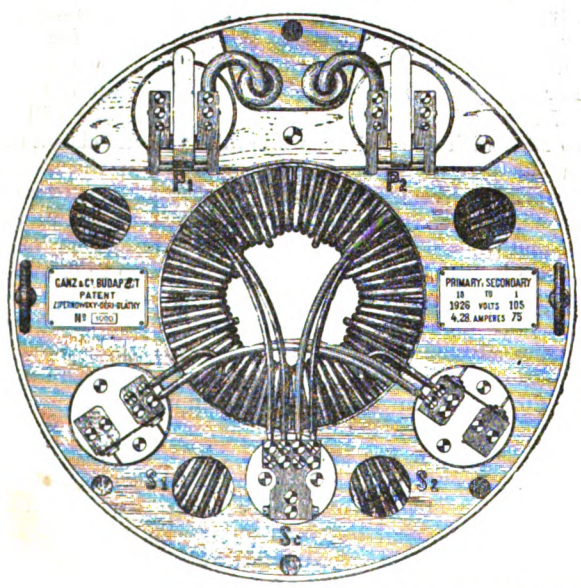
looked like a stout circular ring. (*See* Fig. 8.) This form possessed a multiplicity of disadvantages. The heat generated in the coils themselves escaped with great difficulty. The magnetic resistance of the iron circuit was considerable, and any damage to the coils or insulators could only be repaired by taking the whole apparatus to pieces with great labour. Hence this type of shell transformer gave way to a more practically useful form. In the latest form, a series of sheet-iron discs like flat thin rings, are stamped out; these are built up with interposed paper layers into a circular ring of laminated iron, having a square or rectangular cross section. These discs are held together by radially placed clamping plates (*see* Figs. 9), which divide the ring core into partitions. The primary coils are then wound on the ring, covering it uniformly, and the secondary wire is put outside the primary. Iron discs top and bottom enclose the core and serve as supports for the terminals and fuses. The transformer roughly resembles a water-wheel, and can be rolled about easily when set on edge. On the top plate are fixed porcelain discs, which carry the primary and secondary fuses, which are short slips of fusible metal contained in glass tubes. The transformers are made in various sizes, to transform down generally to 105 and 52 volts, and each secondary circuit has three terminals by which 105 volts can be taken off for incandescence lamps, and 52 volts for arc lamps. The transformers are made in four sizes as follows:—

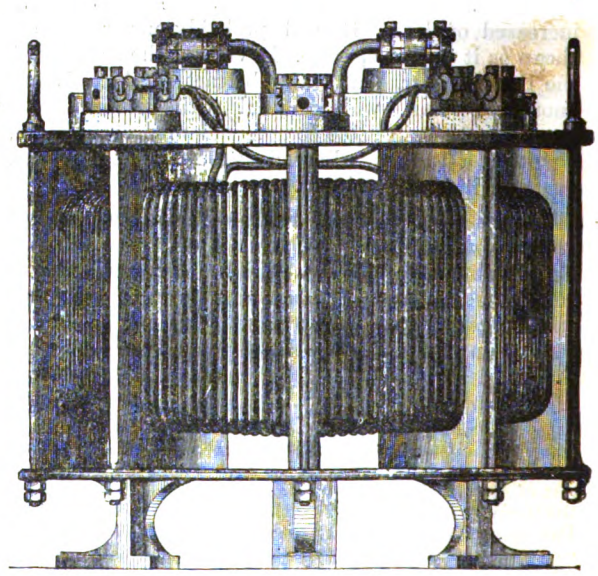
Ganz Transformers.

No.	Output in watts.	Weight in kilogrammes.	Commercial efficiency at full load as given by makers.
1.	1,875	70	92·5
2.	3 750	110	94·5
3.	7,500	180	95·5
4.	15,000	290	96·8

The energy loss in magnetizing the iron is stated to be 5·5, 3·5, 2·5, and 1·5 per cent. respectively at full load in the No. 1, 2, 3, and 4 sizes, and the energy loss in the copper is put at 2 per cent. The primary coils are wound to receive current at 900, 1,800, 2,700, and 3,600 volts respectively in the four sizes, and to transform it down to 105 and 52 at the chief and intermediate terminals on the secondary circuit. The relation in commercial efficiency to the load on the secondary circuit of watts is given by the efficiency curve, as shown in Fig. 10.

This curve is given only on the authority of the manufacturers, but its general accuracy is probably sufficient for the purpose of reckoning the efficiency of the transformer at various loads. It has been confirmed fairly well by the independent tests made by the Frankfort-am-Main Committee in 1890. This committee found that the latest pattern of Ganz transformer had at full load an efficiency of 95 to 96 per cent., at half-load 93 to 94, at quarter load 90, and at eighth load 80 per cent. efficiency. (*Electrician*, Vol. XXIV. (1890), p. 439.)





FIGS. 9.—Ganz Transformer (Zipernowski, Déri, Bláthy), 1890.

The experiments of M. A. A. Roiti,* to be again referred to later on, have also shown the efficiency at full load of a 3,800-watt Ganz transformer to be from 94 to 96 per cent.; but we defer to another chapter the full discussion of the

Digitized by Google

methods by which these values have been arrived at. It is desirable, however, to make here a brief reference to some misleading conceptions which often surround the question of the efficiency of transformers in practical use. It has been frequently pointed out that there is a great difference between the *instantaneous efficiency* of a transformer at any moment, and the *mean efficiency* over any period such as 24 hours, during which it is loaded to very various degrees. The difference between these efficiencies may be considerable, the mean efficiency being often very much less than the maximum efficiency, and depending on the way in which the transformer is used. Given, however, a definite load curve—that is, a curve showing the load in watts on the secondary of the transformer at short intervals of time during the day, and an efficiency

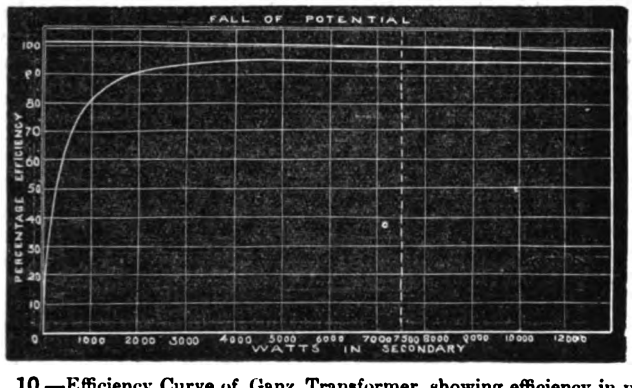

Fig. 10.—Efficiency Curve of Ganz Transformer, showing efficiency in per cents in terms of secondary load.

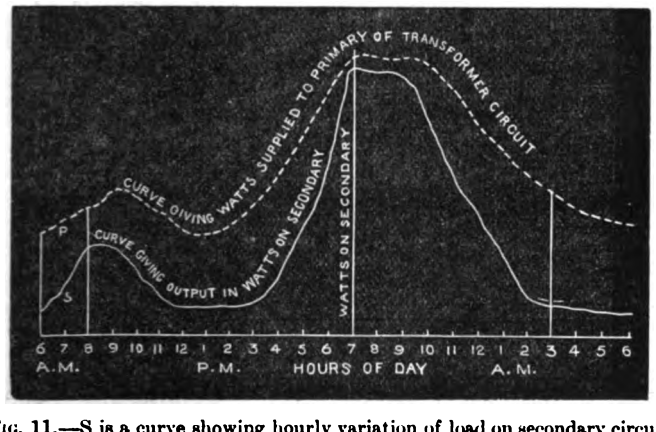
curve such as that in Fig. 10—the mean efficiency may be deduced as follows:—

Let the ordinates of the firm-line curve in Fig. 11 represent the secondary load in watts, or the lamp-load on the transformer, at the various hours of the day. Increase each hourly ordinate of this curve in the ratio of 100 to the number



CURVE GIVING WATTS SUPPLIED TO PRIMARY OF TRANSFORMER CIRCUIT
CURVE GIVING OUTPUT IN WATTS ON SECONDARY
WATTS ON SECONDARY

A.M. P.M. HOURS OF DAY A.M.

Fig. 11.—S is a curve showing hourly variation of load on secondary circuit in watts. P is a curve showing corresponding variation of watts supplied to primary circuit.

denoting the efficiency of the transformer corresponding to the actual secondary load at that hour, which can be done from the efficiency curve giving the relation between efficiency and secondary load. Also if at any hours the secondary circuit is open and the secondary load therefore zero, ordinates must be set up at these points on the same scale proportional to, and representing, the power in watts absorbed by the transformer when the secondary circuit is thus open. Let the new higher ordinates define a curve shown by the dotted line. Then the ratio of the whole areas included between the two curves, firm and dotted, and the base line is a fraction which denotes the *mean efficiency* of the transformer during the twenty-four hours. If the load diagram varies from day to day, a further comparison of the daily mean efficiencies must be made to obtain the real average mean over any period of time, such as a year. It follows that a high efficiency at full load will not give a high mean efficiency unless the efficiency curve of the transformer rises from zero very rapidly to its greatest ordinate. A transformer may have a very high efficiency at full load; but if it absorbs, when the secondary circuit is open, a sensible amount of power, and stands idle twenty hours out of twenty-four, its real commercial efficiency may be brought down easily to 60 or 70 per cent. or less. Further remarks on the bearing of this fact on the economy of working of transformer stations will be reserved until later. In central-station work done by this firm the 7·5 unit, or 7,500 watt transformer, is a very favourite size. The usual practice with Messrs. Ganz and Co. is to "bank" a number of transformers when a large secondary output is required, so arranging them that the primary circuits are all in parallel between the primary mains and the secondary circuits all in parallel with the secondary mains, and then to connect or disconnect transformers according as a larger or smaller output is required. In placing the transformers four methods are adopted. The transformer when one only is

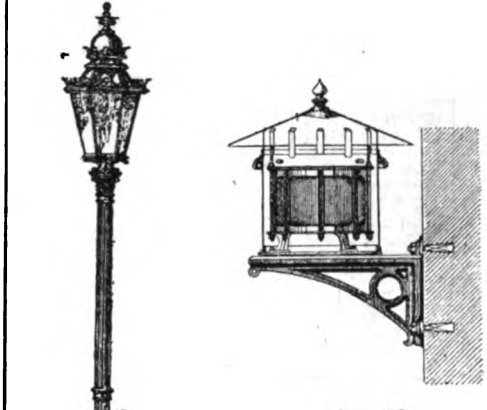

Fig. 12.

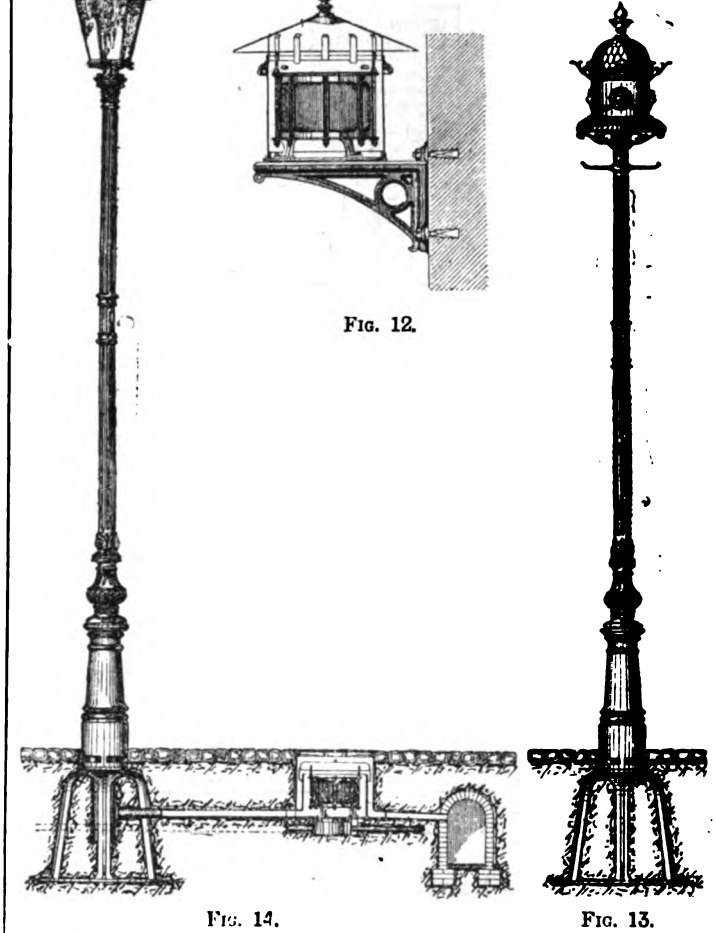

Fig. 14.

Fig. 13.

required at a place can be placed on a shelf enclosed in a weather-tight iron box (*see* Fig. 12), or it may be perched up on an iron pole like a dovecot, an ornamental form being given to the transformer case (*see* Fig. 13), or it may be buried in a watertight iron box (Fig. 14), or some small fireproof dry room in the building to be supplied with current may be set apart as a transformer house, and in which the transformers are arranged on porcelain insulators, on stone or wooden shelves, or resting on iron rails. This latter plan has much to recommend it in the facility it affords for getting at the transformer.

§ 5. **Pressure Regulating Devices.**—If an alternating-current dynamo is supplying current to a group of distant transformers through a cable laid between the localities, and if the load on the secondary circuits of the transformers varies, then the primary current flowing through the supply conductor will vary also. In order that the electric pressure at the terminals of

Digitized by Google

the secondary circuits of the transformers may be kept constant in value, it is sufficient and necessary that the pressure between the primary terminals of the transformers be maintained at a constant value. Assuming that the primaries of the transformers are arranged in parallel between the primary conductors it follows that whatever may be the variation in the primary current, the pressure between the terminals of the primaries of the transformers must remain the same. If the resistance of the cable is R ohms, and its self-induction negligible, and if V is the potential difference between the terminals of the alternator, and v is the potential difference between the terminals of the primary coils at the far end of the cable, then the current in the cable in amperes is approximately equal in magnitude to $\frac{V-v}{R} = C$. Hence, we have $v = V - C R$, and if v is to be kept constant, then it follows that as the strength of the primary current C varies, the potential difference at the terminals of the alternator must vary also, but so that the quantity $V - C R$ remains constant in value. The pressure at the terminals of the alternator must therefore not be maintained constant, but fluctuate with every change in the load on the transformers at the far end of the cable. It has already been pointed out that with the arrangements adopted by Messrs. Ganz and Co., this can be achieved by regulating the strength of the field-magnet current of the excitors; and MM. Zipernowsky, Déri, and Bláthy, have devised an exceedingly ingenious method for regulating automatically the magnetising current of the excitors, in such a manner that the quantity $V - C R$ is kept constant for all values of the secondary loads. The arrangement adopted is called an automatic regulator, and is placed in the central station in some convenient position. It is diagrammatically represented in Fig. 15. A is the alternator, and L_1 L_2 the primary leads, or cable proceeding out from the station. In some convenient position in the station are placed two transformers, T_1 and T_2, called respectively the Shunt and the Series Transformers. The primary circuit of the Transformer, T_1, is placed in parallel across the leads L_1 L_2, and the primary of the Transformer, T_2, is placed in series in one of the leads, L_2. The secondary circuit of T_2 is closed through a suitable resistance, R_2, and the secondary circuit of T_1 is closed through a solenoid, S, and resistances T, R_1 and R_2 as shown; the transformers T_1 and T_2 being so joined up that the secondary electromotive forces in T_1 and T_2 oppose one another as far as producing a current in the solenoid S is concerned. The potential difference between the terminals e and d of T_1 is proportional to the potential difference V between the terminals of the alternator. The potential difference between the points a and b is, or can be, made nearly proportional to the magnitude of the primary current in L_2, and hence to the fall in volts along the cable or to C R. Hence the potential difference between c and b or between e and f can be made proportional to $V - C R$ or to v, the primary pressure at the primary terminals of the transformers. If a voltmeter Vl is joined up between e and f, this voltmeter can be made to read the same value as a voltmeter placed across the secondary terminals of the transformers at the far end of the line. For this pressure at the secondary terminals is proportional to v, the pressure at the primary terminals. Hence the voltmeter Vl can read the pressure at any instant on the lamp circuits, although it is in no way connected directly with them. This voltmeter always indicates a pressure proportional to $V - C R$, which quantity it is necessary to keep constant.

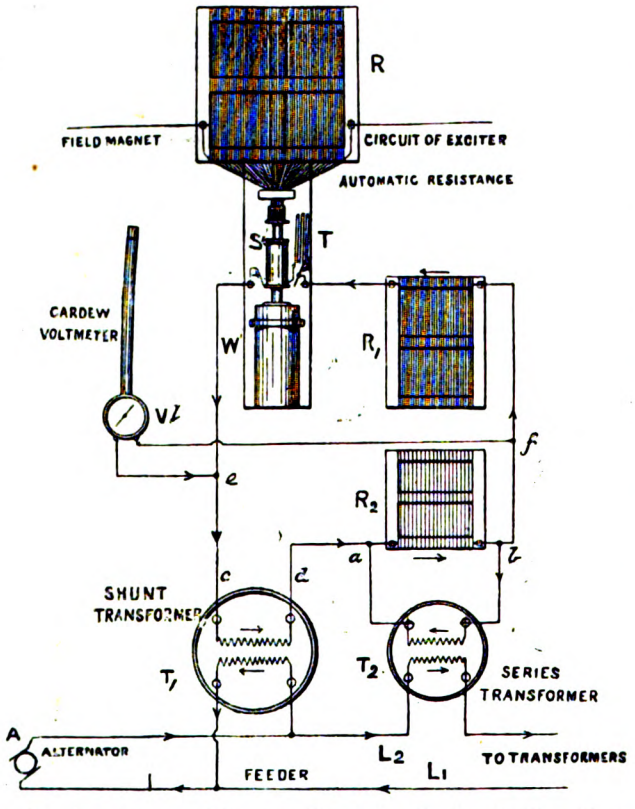

Fig. 15.—Arrangement of Pressure-Regulating Devices in Ganz System.

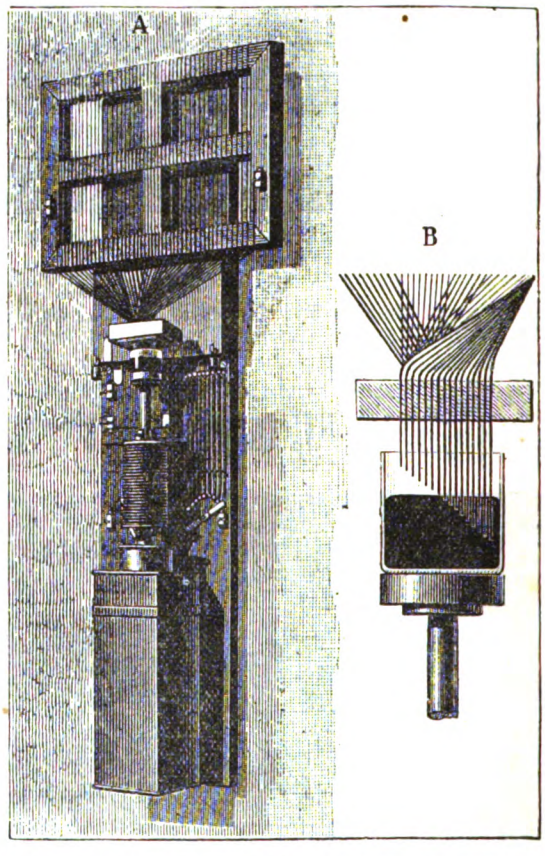

Fig. 16.—Mercury Cup, Float, and Solenoid in Ganz Pressure Regulator

The solenoid S is therefore traversed by a current, which is thus controlled in strength by the outgoing main current C and the terminal pressure V of the alternator. This solenoid is traversed by a tube or rod, partly of iron and partly of brass, the iron part so situated that a current in the solenoid tends to draw it up into the solenoid. This rod is held between guide pulleys, so that it can move quite freely through the solenoid. It carries at its upper end a glass cup full of mercury, and at its lower end is a metal float, by means of which its weight is taken up when the float is immersed in a vessel of water. The diagram in Fig. 16 shows clearly the nature of these arrangements. Above the mercury cup is situated a resistance coil of iron wires, and the terminal wires of the sections into which this coil is divided are brought down into a group of iron wires bevelled off like pan-pipes, and so fixed in a block as to dip into the mercury in the cup (B, Fig. 16). It is easily seen, therefore, that as the mercury cup rises and falls it immerses a greater or fewer number of iron wires, and more or less of the coils on the resistance coil will be short-

Digitized by Google

circuited by this immersion. This resistance coil is in the circuit of the field-magnet coils of the excitors; and hence as the mercury cup moves up or down in obedience to a greater or less attractive force of the solenoid upon the iron rod carrying that cup, so the field strength of the excitors is varied.

The connections are made so that if the current in the solenoid circuit, which is proportional in strength to V—C R, increases, the mercury cup is drawn down, and so intercalates resistance in the fields of the excitors and decreases the strength of the field of the alternators, and *vice versâ*. There is a small rheostat or resistance T in series with the solenoid S, by which large variations of the current in the solenoid can be made by hand, and in the same way large amounts of variation of the fields of excitors can be made by a hand-regulated resistance; and the automatic arrangements then can be set to keep the pressure at the far ends of the feeders constant within a given amount, so as to be independent of the changes of load. The above arrangement may seem at first rather complicated, but it does its work in practice very well, and its practical operation shows it to be one of the few devices of this kind which can be considered to be a thorough success.

The above described elements constitute the distinctive features of the transformer system elaborated by MM. Zipernowsky, Déri, and Bláthy, and we proceed to describe some of the central stations operated by the aid of these devices.

(To be continued.)

REVIEWS.

Practical Electricity in Medicine and Surgery. By G. A. Liebig, jun., Ph.D., Assistant in Electricity, John Hopkins University, &c., and George H. Rohé, M.D., Professor of Obstetrics and Hygiene, College of Physicians and Surgeons, Baltimore, &c. (London and Philadelphia: F. A. Davis.)

The authors of this work very rightly remark in the preface that "A treatise on medical electricity . . . should be eminently practical, and should deal with such matters only as have a direct bearing upon the requirements of the practitioner. The book should be free from unnecessary technicalities, and only so much attention should be devoted to theory as is demanded in the explanation of such phenomena as are presented in the medical and surgical uses of electricity." Although an attempt is made on a subsequent page to justify a departure from this excellent principle, we cannot help thinking that Drs. Liebig and Rohé would have produced a far more useful work had they adhered a little more closely to their original opinion.

The book is divided into three parts, of which the first deals with the general principles of electricity and magnetism, while the second and third parts are devoted to an account of electrophysiology and therapeutics.

In common with many other writers on the subject, the authors appear to have assumed, at the outset, that, as a rule, medical men are profoundly ignorant of the veriest axioms of electricity, and hence the book commences with a lengthy description and explanation of the effects produced, by rubbing together "a piece of glass and a stick of resin, or a piece of ebonite and a silk rag." Subsequently, a tendency is shown to form a somewhat higher estimate of the capacity of their readers. Allusions are made to "sines," "shunts," and "torsion," and we are treated to pages of formulæ and to abstruse explanations of equally abstruse laws, the practical application of which to the subject of medical electricity it is somewhat difficult to determine; nor are we assisted in doing so by any very definite references to these formulæ and laws in subsequent parts of the work. As an instance of the unpractical character of this part, we would point out that no less than seven pages are devoted to the consideration of various forms of galvanometers; the student is then met with the somewhat *naïve* remark that "those galvanometers which have heretofore been mentioned are intended almost exclusively for laboratory purposes!"

Whether or not the profound ignorance to which we allude actually exists (which we doubt), we cannot help thinking that the attempt to combine in the short space of some hundred pages or so, an elementary treatise on electricity, with explanations of the more complicated questions which arise, is, to say the least, unfortunate, and leads to a crudeness and want of perspicuity which seriously detract from the merits of the whole work. The chapter dealing with "Batteries and Cells" is, as far as it goes, a considerable improvement on the two preceding chapters, but even here we notice the same unpractical tendency. The Daniell, the Grove, and the Bunsen cells are excellently figured and described, but we can find no allusion in this part of the work to the bichromate cell, nor to the well-known and popular Leclanché element. This omission is the more apparent, because, on page 220, the Leclanché cell is referred to as being one that "fulfils most of the desiderata" of a stationary battery; and on page 227, the opinion is expressed that, in spite of their "shortcomings, the bichromate batteries remain, at present, our best type of portable batteries." The account given of the principles and mode of action of "storage electricity" is clear and valuable; very rightly, exception is taken to the use of the word "storage," as conveying a misleading impression of the *modus operandi* of such batteries, but the word is retained in deference to popular opinion.

It is hardly necessary in these columns to express in detail our opinions upon Parts II. and III., dealing, as these Parts do, more particularly with electro-physiology and therapeutics. They appear to be well written and concisely expressed, and should, we think, be of considerable value to the practitioner. We cannot, however, fail to be struck by the apparent independence of these two Parts of the work upon the Part immediately preceding. To all intents and purposes the perusal of the electrical sections in any standard work upon natural philosophy or physics might, and we think with advantage, be substituted for Part I.; and yet Parts II. and III. would still be readily understood, and possibly more fully appreciated. The last hundred pages of the work are devoted to the methods which have been employed in the application of electricity in various diseases. The list of diseases is somewhat a portentous one; to us it appears that there are but few of the troubles which "human flesh is heir to" but have been more or less successfully alleviated by the use of electricity. In many cases the improvement seems, as far as we can judge, to have been due solely to the electrical applications; in others, and notably in the case to which the plates facing page 372 refer, the electricity has been associated with other powerful remedies, and it is therefore very difficult to determine exactly the amount of credit due to each.

The book is well got up and excellently printed; the illustrations, which are very numerous, are many of them original, while others are derived from such well-known sources as Erb's "Elektrotherapie," von Ziemssen's "Elektricität in der Medicin," &c. The value of the work would be enhanced by the introduction of a fuller index, which might also be made to do duty as a glossary, or a separate glossary should be added.

Technology Quarterly. May, 1890. Massachusetts Institute of Technology, Boston.

The Paper on "Tests of Incandescent Lamps," by Mr. Puffer, which concludes this number, contains little that is of interest, even to the lamp-maker. The diagrams to show the distribution of the light are arranged to overlap each other in a very confused way, apparently to save space. Going backwards, there is a brief article on an early form of Pentane lamp, and an article on the engineering laboratories of the institute. These appear to be splendidly equipped with numerous testing machines, tanks, and extensive apparatus for hydraulic experiments, a triple-expansion experimental steam engine of 150 horse-power, besides other engines of 80, 40, 16, and 8 horse-power dynamometers, cotton machinery, looms, and many other important machines, besides class-rooms, and drawing offices. The first two items of the number are of very great value; the one, a lecture on "Some of the present aspects of Education," by the late W. P. Atkinson, and

Digitized by Google

the other, a short memorial of the author. For beauty of style, and for a quiet and impartial tone in handling the merits of classical and technical education we have rarely seen its equal. Much has been written in our periodicals in a didactic and sometimes in an aggressive spirit, and we strongly recommend all who are interested in educational matters to study this admirable lecture, for which some rather superfluous apologies are made by the editor.

At the risk of spoiling the literary value of the whole, we propose shortly to extract those parts which bear directly upon scientific education.

The Wimshurst Electrical Influence Machine. By WILLIAM PHILLIPS MENDHAM. (Bristol: King, Mendham and Co.)

This is an illustrated brochure of about 60 pages, briefly describing the action of the Wimshurst machine, and giving a few practical hints with regard to its management. The greater portion of the book is taken up with descriptions of the experiments which can be performed by aid of this machine. It is to be regretted that the author has confined himself entirely to an account of the usual popular lecture type of experiments.

Turning Lathes: a Manual for Technical Schools and Apprentices. Edited by J. LUKIN, B.A. (Published by the Britannia Company, Britannia Works, Colchester.)

This little book is very clearly written, and will have a wider sphere of usefulness than that suggested by its title. The author has treated his subject methodically, starting from the very beginning, and keeping constantly before his reader the need of patience and care in detail when commencing lathe work if any real proficiency is to be attained. While embracing wood and metal turning, and giving a chapter on metal-spinning, it is the elementary details of each to which special attention is paid; and the aim of the author has been to explain the sources of disappointment to the beginner, and how his difficulties may be avoided and overcome. Anyone who thinks he has only to buy a lathe with a compound slide rest in order to turn out good work is warned off, and he is told very plainly that if he wish to succeed he had better buy a cheap lathe, and master wood-turning by hand before he uses the rest. In fact, no one is encouraged to buy a lathe unless he really means to take the trouble and give the time to master the instrument. The difficulties to be overcome before satisfactory work can be turned out are insisted on, one might almost say, to a disheartening extent, were it not that the best method of overcoming these difficulties by practice, and using thought with the tools, are pointed out at the same time. Many little hints for making apparatus and devices by which the use of costly tools may be avoided are given, which will be useful to many besides the tyro. It is rare to find a book written for beginners by an author who is master of his subject without his presupposing they possess some of his knowledge.

THE EFFICIENCY OF THE TRANSFORMER.*

BY CALVIN HUMPHREY AND WILLIAM H. POWELL.

The results presented in this Paper are supplementary to the work of Prof. Ryan and Mr. Merritt in the same line, presented to the Institute last December. The 10-light transformer which they tested was found to have a remarkably heavy loss on open circuit, which was shown to be due almost entirely to hysteresis in the iron. The transformer gave an efficiency of 86 per cent. at normal load and an "all-day" efficiency of about 40 per cent.

In our work on a 40-light transformer of the same design (the two coils placed side by side in a core of laminated plates, *see* Fig. 1), but of more recent manufacture, the loss on open circuit was found to be about one-half as great as in the 10-light transformer. Its efficiency reached 96·2 per cent. at normal load, and the "all-day" efficiency would be about 90 per cent.

The method employed in the work is substantially Prof. Ryan's method. The instantaneous values were obtained by means of a commutating device, attached to the alternator. This device consisted of a wooden disc, mounted rigidly on the shaft of the alternator, with a steel contact at one point in its periphery, which made contact with a small piano wire brush once every revolution. The holder carrying the piano wire brush was attached to a pointer, which moved over a scale and indicated the position of the brush for a given reading. Then, evidently, if the brush which completes the circuit through the contact be altered in position, values can be obtained for different points on the curves of E.M.F. and current.

A quadrant electrometer was used to measure the primary E.M.F., secondary E.M.F., and primary current. A condenser was connected in parallel with the electrometer. The primary current was measured by the fall of potential through incandescent lamps placed in series with the primary of the transformer. These lamps were carefully calibrated at different temperatures. Then, knowing the resistance of the lamps and the potential difference at the terminals, the current flowing at once becomes known.

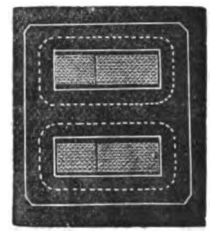

FIG. 1.

To measure the primary E.M.F. twenty-two 50-volt lamps were placed in series across the primaries. The electrometer was connected around two of these lamps, and the whole number calibrated, in order to know what part of the total impressed E.M.F. was measured. The secondary E.M.F. was measured direct. The secondary current was measured by means of an electro-dynamometer, which was carefully calibrated both before and after the experiments, and was found to be constant. The commutating device was placed in series with the electrometer.

In obtaining the Ewing curve of hysteresis of the iron core of the transformer, current from a storage battery was sent through the secondary circuit, and the magnetisation set up in the core was measured by the *kick* on a ballistic galvanometer in the primary circuit. The current in the secondary was gradually increased until the intensity of magnetisation corresponded with the maximum magnetic density of the transformer when working on a 1,000-volt circuit. The current was then decreased gradually until zero was reached. It was then reversed and the method continued until a complete cycle of magnetisation had been covered.

It is worthy of mention that this method, which gives something so definite and fundamental in the treatment of the alternating current, has only come into use within the past year, and the task of getting true instantaneous values of the complete waves of E.M.F. and current, which has always been considered too tedious for ordinary patience to deal with, was accomplished with ease in this work in 45 minutes. A calibrated scale for the electrometer readings added very much to the facility with which observations could be taken.

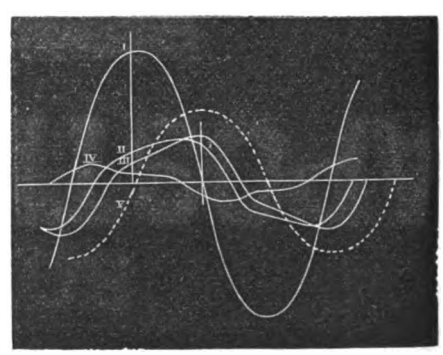

FIG. 2.

I. Primary E.M.F. [maximum 1,300 volts].
II. „ Current [maximum 0·11 amp.].
III. „ „ with Foucault currents eliminated [max. 0·12 amp.].
IV. Foucault current component [maximum 0·05 amp.].
V. Curve of magnetisation.

The marked improvement of the 40-light transformer over the 10-light is due, we believe, to an improvement in the magnetic properties of the iron and a fewer number of turns in the coils, made possible by the better grade of iron.

In the 10-light transformer, Foucault currents were very effectually weeded out by the interposition of sheets of paper between

* Abstract from a Paper read before the American Institute of Electrical Engineers, New York June 17, 1890.

Digitized by Google

the laminated sheets of iron; in the 40-light the oxide of iron on the surface of the plates was the only safeguard against Foucault currents.

The form and extent of the open-circuit curves show the loss due to hysteresis and the slight loss also due to Foucault currents. The presence of Foucault currents is indicated by the fact that the maximum of the primary current wave does not occur simultaneously with the zero of primary E.M.F., but a little before. It is found upon analysis of the primary current curve into its elements, hysteresis and Foucault currents (*see* Fig. 2) that the Foucault current component occurs 120deg. in advance of the theoretical magnetisation curve, and not 90deg. in advance, as has generally been assumed. Therefore, when superimposed upon the hysteresis curve, it introduces a component in advance, and thereby decreases the lag of the primary current.

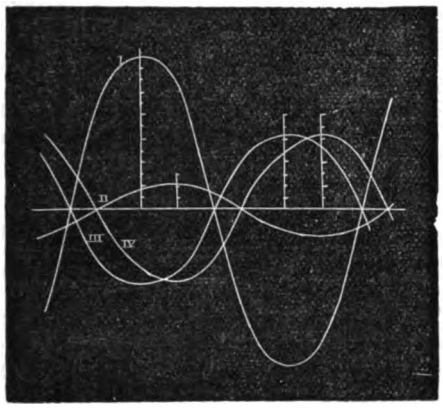

FIG. 3.—Small motor on secondary.

I. Primary E.M.F. [maximum 1,300 volts].
II. „ Current [maximum 0·55 amp.].
III. Secondary E.M.F. [maximum 63 volts].
IV. „ Current [maximum 8 amps.].

The lag of the primary current behind the primary E.M.F. is seen to be greatest when the secondary circuit was open, and decreases as a non-inductive load is introduced into the secondary circuit. This tendency of the lag of the primary current to decrease with increase of load continues until the curve of primary current comes into unison with the curve of secondary E.M.F.

The secondary E.M.F. is in unison with the primary E.M.F. on open circuit, and gradually falls behind as the load increases on the secondary. This is doubtless due to the leakage of lines of force arising from the enormous magnetising forces at work in opposition to one another in the primary and secondary ciruits.

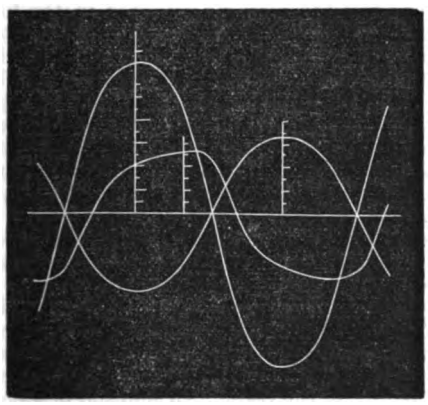

FIG. 4.

Inductive resistance in circuit of secondary.
Maximum primary volts, 1,300.
„ „ current, 0·13.
Secondary volts, 65.

When an inductive resistance is introduced into the secondary circuit, the lag of the primary current is greatly increased, as shown by the set of curves in Fig. 3. The inductive resistance used in this case was due to a small alternating-current motor. The curve of secondary current was also taken, and found to lag behind the secondary E.M.F., and to be in unison with the primary current. About 5·5 amperes flowed in the secondary, and yet the lag of primary current is as great as on open circuit.

Fig. 4 shows the relation of primary current and primary E.M.F. when the secondary was closed through the secondary of a 20-light transformer, whose primary remained open. The current curve shows a distinctive lag from the inductive resistance and is altered in form to a great extent.

The outside loop in Fig. 5 is the loop of total hysteresis loss and Foucault currents—deduced from the open circuit curves in the following manner: The current which flows to maintain the counter E.M.F. of the transformer on open circuit obviously includes the losses due to Foucault currents and hysteresis. If, thon, a magnetisation curve, whose maximum has been computed, be drawn in

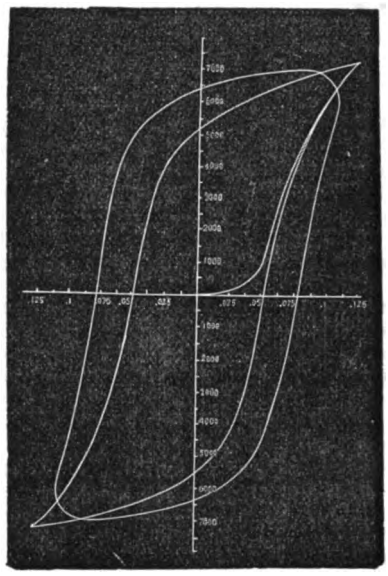

FIG. 5.

Ordinates, in lines of force per square centimetre.
Abscissæ, Amperes in primary.

90deg. behind the curve of primary E.M.F. and of the same form —since it is a function of the E.M.F.—and a curve be plotted using ordinates of primary current and abscissæ, and corresponding values of lines of force from the theoretical magnetisation curve, as ordinates, the outside loop in Fig. 5 is obtained.

The inside loop is the ordinary Ewing curve of hysteresis loss found by carrying the iron slowly through a complete cycle of magnetisation. The lines of force were computed from the *kick* on a ballistic galvanometer. This curve has in it no Foucault current effects. If, then, we reverse the above method, and from the Ewing curve and the magnetisation curve deduce a primary current curve, we shall have a curve representing hysteresis (for this iron) loss.

This was done; and it is of special interest to note that the form of curve obtained in this manner is identical with the open circuit curve of the 10-light transformer in which Foucault currents were suppressed by the interposition of sheets of paper (*see* curve III., Fig. 2). Having, then, two curves plotted to the same scale, one epresenting total loss and the other hysteresis loss, if we subtract rdinates of the latter from corresponding ordinates of the former,

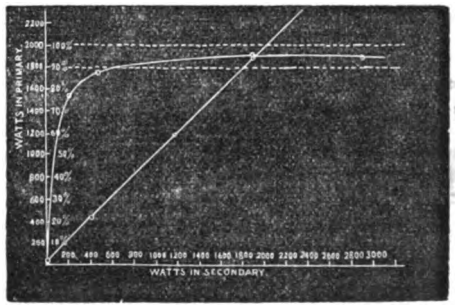

FIG. 6

a curve representing the component due to Foucault currents will be obtained (curve IV., Fig. 2). It was in this manner that the analysis before referred to was made. The position of the Foucault current component accounts for the round corners in the outside loop of Fig. 5.

The efficiency curve shown in Fig. 6 is the ratio between the energy of the primary circuit as indicated by the mean ordinate of the watt curve, and the energy of the secondary circuit as expressed

Digitized by Google

by the product of the $\sqrt{\text{mean}^2}$ readings for E.M.F. and current. The coercive force is equal to 0·8 C.-G.-S.

These considerations go to show that the loss due to the reversal of polarity of the iron, which perhaps must always be present, may be reduced almost indefinitely by a proper study of the magnetic properties of the iron used.

THE ELECTRO-DEPOSITION OF PLATINUM.*

BY WM. H. WAHL.

(Concluded from page 262.)

Of the salts that may be formed from platinic hydrate by solution in acids (and in part by suitable combination with the corresponding alkaline compounds to form double salts), three only may be named as sufficiently useful to yield practically valuable results in plating. These are the phosphates, oxalates, and acetates, of which also it is practicable to form double salts with the alkalies, soda, potassa, and ammonia, which yield bright, reguline, and adherent plating.

Oxalic acid, so far as I have been able to determine, of all the oxygen acids, is the best solvent of platinic hydrate, dissolving it even in the cold, but with great energy when aided by heat, and forming platinous oxalate, with evolution of carbonic anhydride. From this brownish-black or deep blue solution (according to concentration), brilliant reddish-brown scales of the salt separate abundantly and readily from the hot saturated solution. A saturated aqueous solution of the simple oxalate prepared from the hydrate as above described, will yield bright, reguline, adherent platinum when electrolyzed with a comparatively weak current, with evolution of carbonic anhydride at the anode. With a stronger current hydrogen also appears at the cathode. This bath may be maintained indefinitely at normal metallic strength by observing the precaution to add oxalic acid and platinic hydrate in small quantities from time to time; or by keeping constantly at the bottom of the bath some platinic hydrate, and adding oxalic acid in crystals or powder from time to time as may be required to keep the bath saturated; or, what is much to be preferred, making a supply of platinous oxalate from platinic hydrate in the manner previously described, and keeping an excess of this present in the bath at all times. This bath has the same advantages as are possessed by the above-described alkaline platinate baths, of being capable of indefinite maintenance at normal metallic strength, and of introducing no substances that will cause its deterioration by the formation of secondary decomposition products.

Phosphoric acid also is a solvent of platinic hydrate. A dilute aqueous solution of this acid will dissolve a small quantity of the metallic hydrate in the cold, and a much larger quantity when aided by heat. With increasing concentration, the solvent power of this acid for platinic hydrate is correspondingly increased. The resulting solution of phosphate of platinum, according to the degree of concentration, will be wine-yellow to cherry-red in colour, and with a comparatively weak current, will yield bright, reguline and adherent platinum on metallic surfaces properly prepared to accept the same. The electrolysis of this compound also does not involve the formation of deleterious secondary products, the result of the operation being the separation of the metal at the cathode and of the acid radical at the anode—and of the elements of water which are evolved as gases respectively from anode and cathode. In the operation of the bath, therefore, it will become more and more acid as the metal is withdrawn by the accumulation therein of the phosphoric acid set free at the anode. The maintenance of the metallic strength of the bath, therefore, may be effected as in the foregoing cases by having present therein at all times a small quantity of platinic hydrate or by the addition at the end of each day's work of the quantity of the metallic hydrate which will be required to restore the amount of metal withdrawn. This bath must be worked very acid, and the solution of the platinic hydrate to maintain the strength of the bath must be facilitated by heating, as the solvent power of phosphoric acid for platinic hydrate is much inferior to that of oxalic acid. The double phosphates of platinum with certain of the alkalies may be formed, which will be capable of yielding a deposit of bright, reguline and adherent metal, and of being maintained approximately at normal metallic strength in the same manner as I have set forth above. The best results I have obtained with the ammonio-platinic phosphate, prepared by adding to the solution of platinic hydrate in phosphoric acid sufficient aqua ammoniæ to cause the same to give an alkaline reaction, which point will be indicated by the formation of a greyish precipitate that will not disappear on stirring; then restoring the acidity of the solution by adding free phosphoric acid in excess, upon which the precipitate readily dissolves. The resulting solution is yellowish or brownish, and yields superb plating; though, on account of the greater difficulty of maintaining its metallic strength by the solution of the hydroxide, it is not so well adapted as the oxalate for the work of electro-deposition on the large scale. The sodio-platinic phosphate formed in a manner precisely analogous to the ammonia compound just described, will also yield bright, reguline, and adherent plating; but I have observed that the soda salt is less freely soluble than the corresponding ammonia compound, and consequently more difficult than the latter to maintain of normal metallic strength.

The presence of acetic acid in an alkaline bath appears favourably to influence the quality of the plating yielded, giving the deposited metal a whiteness approaching that of silver; and furthermore, acetic acid yields only the elements of water and volatile compounds, when electrolised and therefore does not contaminate the electrolytic bath by forming deleterious secondary products.

The foregoing comprise the compounds that I have found to yield the most satisfactory results in platinum plating. I append directions for the preparation of the several electrolytic baths above described, and indicate what I have found to be the most favourable conditions for working them.

Directions for Preparing the Electro-Plating Baths.—For the alkaline platinate bath, the following directions may suffice:—

Platinic hydrate	2oz.
Caustic potassa (of soda)	8oz.
Distilled water	1gallon

Dissolve one-half of the caustic potassa in a quart of distilled water; add to this the platinic hydrate in small quantity at a time, facilitating solution by stirring with a glass rod. When solution is effected, stir in the other half of alkali dissolved in a quart of water; then dilute with enough distilled water to form one gallon of solution. To hasten solution, the caustic alkali may be gently heated; but this is not necessary, as the platinic hydrate dissolves very freely. This solution should be worked with a current about two volts and will yield metal of an almost silvery whiteness upon polished surfaces of copper and brass, and quite freely. There should be slight, if any, perceptible evolution of hydrogen at the cathode, but a liberal evolution of oxygen at the anode. I have observed that the addition of a small proportion of acetic acid to this bath improves its operation where a heavy deposit is desired. The anode may be of platinum or carbon, and owing to the readiness with which the metal is deposited an excess of anode surface is to be avoided. Articles of steel, nickel, tin, zinc, or german-silver, will be coated with black and more or less non-adherent platinum; but by giving objects of these metals a preliminary thin electro-deposit of copper in the hot cyanide bath, they may be electro-platinised in the alkaline platinate bath equally as well as copper. The bath may be worked hot or cold, but it is recommended to work it at a temperature not exceeding 100°F. It may be diluted to one-half the strength indicated in the formula, and still yield excellent results. The surface of the objects should be highly polished by buffing, or otherwise, prior to their introduction in the bath, if the resulting deposit is designed to be brilliant.

The deposition of platinum takes place promptly. In five minutes, a sufficiently heavy coating will be obtained for most purposes. The deposited metal is so soft, however, that it requires to be buffed very lightly. A heavier deposit will appear grey in colour, but will accept the characteristic lustre of platinum beneath the burnisher.

The oxalate solution is prepared by dissolving one ounce of platinic hydrate in four ounces of oxalic acid and diluting the solution to the volume of one gallon with distilled water. The solution should be kept acidified by the occasional addition of some oxalic acid. The simplest plan of using this bath, and which requires no attention to proportions, is simply to work with a saturated solution of the oxalate, keeping an undissolved excess always present at the bottom of the vessel. An addition of a small quantity of oxalic acid now and again will be found advantageous. The double salts of oxalic acid with platinum and the alkalies may be formed by saturating the oxalate of the desired alkali with platinic hydrate and maintaining the bath in normal metallic strength by the presence of an undissolved residuum of platinous oxalate.

The double oxalates are not so soluble in water as the simple salt. The oxalate baths, both of single and double salts, may be worked cold or hot (though not to exceed 150°F.), with a current of comparatively low pressure. The metal will deposit bright, reguline and adherent on copper and brass. Other metallic objects must receive a preliminary coppering as above. The deposited metal is dense, with a steely appearance, and can be obtained of any desired thickness.

The deposit obtained in the oxalate baths is sensibly harder than that from the alkaline platinate bath, and will bear buffing tolerably well.

* Read at the meeting of the Chemical Section of the Franklin Institute Philadelphia, May 20, 1890.

Digitized by Google

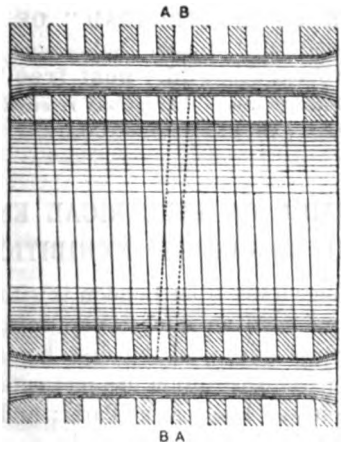
The phosphate bath may be prepared by the following formula:—

Phosphoric acid, syrupy (sp. gr. 1·7)	8oz.
Platinic hydrate	1—1½oz.
Distilled water	1 gallon.

The acid should be moderately diluted with distilled water, and the solution of the hydrate effected at the boiling temperature. Water should be added cautiously from time to time to supply that lost by evaporation. When solution has taken place, the same should be diluted with sufficient water to make the volume one gallon. The solution may be worked cold or warm to 100°F., and with a current much stronger than that required for the platinates and oxalates. The ammonio- (and sodio-) platinic phosphates may be formed from the simple phosphate by carefully neutralising the solution of the phosphate with ammonia (or soda); then adding an excess of phosphoric acid, or enough to dissolve the precipitate formed and an additional quantity to ensure a moderate amount of free phosphoric acid in the bath. The phosphate baths will be maintained of normal strength by additions of platinic hydrate, the solutions of which will have to be assisted by heating the bath, preferably at the close of each day's work. The metal yielded by the electrolysis of these phosphate solutions is brilliant and adherent. It has the same steely appearance as that exhibited by the oxalate solutions, but to a less pronounced degree. The physical properties of the deposited metal are in other respects like those described in connection with that obatined from the oxalate baths.

CHAMBERLAIN'S COMPOSITE "WAVE" PINION FOR ELECTRIC CARS.*

The high speed at which electric motors are required to operate in order to secure a proper efficiency has necessitated the employment of gearing to reduce the speed of the armature shaft to that of the car axles. The noise and vibration accompanying the employment of solid gear-wheels, however, soon became apparent, and means for overcoming both were applied, which consisted in the substitution of pinions built up of alternate layers or discs of steel and a variety of substances, such as raw hide, fibre, &c. These composite pinions, it is true, largely reduced the troubles formerly



experienced, but they introduced others which those operating electric railways have found to be of considerable moment. These consist principally in the fact that, owing to the layers of the composite pinion being placed in planes at right angles to the axis of the shaft, the wear on the all-metal gear-wheel is confined almost wholly to the parts opposite. The result of this is that circumferential grooves are worn in the all-metal gear, which leave ridges at the parts opposite the rawhide. The wear being thus confined to a portion only of the all-metal wheel, the same is more rapidly worn away and its working life is considerably shorter than would be the case were the wear equally distributed.

While the non-resonant qualities of the composite gear were highly desirable, it was manifest that an improvement designed to afford an even wear of both pinion and gear was of not less importance; and this has been effected in a very simple and ingenious manner by Mr. Jacob C. Chamberlain, of this city.

The desired object has been accomplished by placing the alternate layers of metal and rawhide of which the pinion is composed at a slight angle or cant to the axis of the wheel, so that the metal portions in bearing on the all-metal wheel travel laterally upon the same in a worm-like or "wave" motion, so as to distribute the wear.

The construction of a pinion built up in this manner will be readily understood by an examination of the sectional drawing shown in the figure. Here it will be noted the steel disc occupies the position A A at one point; during the next half-revolution, however, on account of its slant, it will have assumed the position shown in the dotted lines B B. The result of this is that each tooth of a disc bears in part on a portion of the engaging wheel different from that engaged by the preceding tooth, thus shifting the wear and distributing it over the whole working face of the all-metal wheel. To fully accomplish this result, it is necessary to give a lateral displacement between opposite diameters of the discs equal to the thickness of the rawhide discs. It is also necessary that the number of teeth on the composite pinion should not be exactly divisible into the number of teeth on the all-metal wheel, and it is desirable that the numbers of teeth should be prime to, or incommensurable with one another, so that each tooth on the pinion shall be brought into engagement with each tooth on the gear-wheel. To prevent the rawhide discs from slipping when clamped between the metal discs, the end faces of the latter are provided with projections, struck up out of the surface of the discs like the teeth of a file, and these grip the rawhide securely. The actual results are excellent.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—MONDAY, July 14th.

Central London Railway Bill.

The Select Committee of the House of Lords on this Bill resumed their inquiry on Monday, under the presidency of Lord Henley. Among the witnesses called was Mr. Henry Gotto, of the firm of Parkins and Gotto, Oxford-street. He was of opinion that there was no congestion of the traffic in Oxford-street, except at Tottenham Court-road and Oxford-circus, and he had noticed that the traffic was considerably less since Shaftesbury-avenue had been opened. He expressed the opinion that the carting of material during the construction of the line would cause injury to business.

Mr. MARSHALL (of the firm of Marshall and Snelgrove) was next examined. He was of opinion that the cartage of material would cause damage to the rateable value of property. He did not object to an electric railway, but wanted it tried somewhere else.

Mr. JEUNE, Q.C., appearing for the Ecclesiastical Commissioners and St. Paul's Cathedral, then addressed the Committee, and called evidence in support of his case, and the Committee adjourned.

TUESDAY, July 15th.

On the further consideration of this Bill, Mr. PENROSE, architect to St. Paul's Cathedral, was cross-examined by Mr. Pember. He believed the clay under St. Paul's was at a great depth, and over it, according to Sir Christopher Wren, was water-bearing sand, which he thought would tend to run in the direction of the proposed line. If the promoters made use of this power of deviation they ought to keep in the solid London clay, under which circumstances he did not see any objection. The removal of water might cause a subsidence under St. Paul's, and if the clay happened to be rotten there was danger of its slipping.

Mr. EDWARD BOURNE LEWIS, C.E., said that, in his opinion, were the clay to begin slipping, as was frequently the case, it was quite possible that it might interfere with the foundation of St. Paul's, and so cause injury to that building. He mentioned that injury had happened to the premises of the National Safe Deposit Company in the Poultry through the slipping of the clay, notwithstanding the fact that it had a foundation of 6ft., and in some places 15ft., of concrete. He was strongly of opinion that the construction of a station in the vicinity of St. Paul's was a risk that ought not to be run.

Sir ALEXANDER RENDEL supported the evidence of the other engineers called in opposition to the scheme.

The Committee adjourned.

WEDNESDAY, JULY 17th.

On Wednesday the Committee engaged in considering this Bill concluded its proceedings.

Mr. LITTLER, Q.C., proceeded to addressed the Committee on behalf of the Metropolitan Railway Company, and of frontagers in Paddington. It was proposed, he said, to adopt an entirely new system of working which had not turned out to be an unqualified success on the City of London and Southwark Subway. By passing the Bill the Committee would be doing an injury by preventing the proper solution of this question, namely, the construction of a new street parallel with Oxford-street. Having regard to all the circumstances which had been laid before their lordships, he asked them to say that the Bill should not be allowed to proceed further.

At the conclusion of Mr. Pember's speech for the promoters the room was cleared.

After the Committee had deliberated in private for about a quarter of an hour, counsel and parties were called in.

The CHAIRMAN, in announcing the decision of the Committee, said—The Committee have given very careful consideration to the evidence which has been laid before them, and we have come to the conclusion that the preamble of the Bill is not proved.

The inquiry then terminated.

THE INSTITUTION OF ELECTRICAL ENGINEERS AT THE EDINBURGH EXHIBITION.

To hold meetings away from London is with the Institution of Electrical Engineers an almost new departure. We say almost new, because this is not the first, but the second time in its history that the Institution has met outside its domicile. The first occasion was last year at Paris; and the success of that meeting was the best proof that the new departure has been a step in the right direction. It is only surprising that the Institution should not have begun much sooner than it did to vary their place of meeting according to circumstances. This policy has been pursued for years past by a kindred society, viz., the Institution of Mechanical Engineers, and has greatly contributed to the practical value of the work done by that body. If during the last ten years the Institute of Electrical Engineers had held meetings at the more prominent Electrical Exhibitions, such as Paris, Munich, Vienna, Philadelphia and London, we should now be able to find in its "Journal" authentic records of the conditions of applied electrical science at the various dates; and such information, apart from purely historic interest, would have been of great practical value. The opportunity has not been taken advantage of until last year; but now that a beginning has been made it is to be hoped that the Institute, as a body, will continue the policy which has found practical illustration at their extraordinary general meeting in Edinburgh.

Digitized by Google

That this meeting was on the whole a great success is admitted on all hands, and in point of numbers it exceeded that of last year held in Paris. The idea of inviting the Institution of Electrical Engineers to visit the Edinburgh Exhibition as a body originated, we believe, with Mr. A. R. BENNETT, the Vice-Chairman of the Executive Council of the Exhibition, and was taken up by the other members of the Council who have co-operated with Mr. BENNETT in this matter. The programme elaborated by these gentlemen was both instructive and entertaining, the entertaining part, however, predominating; which is as it should be. Electrical engineers, like other professional men, are not over-much fond of hard work towards the end of summer, when thoughts of a holiday and rest begin to assume tangible shape; and therefore it is well to dilute a moderate amount of instruction with a rather large dose of pleasure; and that is what has been done at the Edinburgh meeting. We had there, Papers and inspections of exhibits for work; and a *conversazione*, excursions to the Forth Bridge and on the Union Canal for play,

As regards the Papers, we have already commented upon the first Paper, read by Dr. WALMSLEY, in another column, and need therefore not refer to it at greater length in this place than to say that it was just the kind of Paper wanted on such an occasion. The Paper by Prof. AYRTON and Messrs. LAMB, SMITH, and WOODS, on "The Working Efficiency of Secondary Cells," which was read on Wednesday morning, was, however, of too deeply scientific a character for an assembly in holiday mood, and did not receive an adequate discussion. The authors have done an enormous amount of experimental work by means of specially constructed apparatus, and have given in their Paper the results obtained in a condensed form convenient for reference. A Paper of this kind cannot be thoroughly appreciated except after a very exhaustive discussion; and, in the absence of several of the foremost men who have done practical work in storage batteries, the discussion could not possibly be of that character. Some of the results arrived at by the authors are of great practical importance. They find, for instance, that charge and discharge tests of storage batteries may be extremely misleading. If such batteries be thoroughly well charged up before being tested they contain a large store of energy, which can only be drawn out in repeated discharges; and consequently the efficiency tests of the first few charges and discharges give results which are too high. The general conclusion arrived at by the authors as regards efficiency is, however, very encouraging. They find that in steady work with maximum charging and discharging currents the quantity efficiency reaches 97 and the energy efficiency 87 per cent., results decidedly better than most electricians believe to be possible.

On Tuesday afternoon the members of the Institution were conducted through the Exhibition by Dr. WALMSLEY and Mr. BENNETT. Personally conducted tours of this kind have many advantages. In the first place a great deal of time is saved by not having to look at exhibits which may, after prolonged inspection, turn out to be hardly worth that trouble, and in the second place, the attendance of exhibitors is thereby ensured. In the present case several of the more important exhibitors had either come specially to Edinburgh to be personally in attendance at their stalls when the members of the Institute came to visit them, or they had sent representatives capable of giving intelligible explanations of the exhibit —a quality not always possessed by the usual run of attendants at Exhibitions. As a rule, the person in charge of a stall knows very little about the construction and working of the machinery under his care, and the little he knows he thinks he must keep from the visitor, whose inquisitiveness is not always viewed with favour. Under such circumstances the amount of mental labour required to elicit trustworthy information is sometimes very considerable. The inquiring visitor must adapt his questions to the intellectual capacity of the man in charge, and arrive by a slow process of cross-examination at information which the less suspicious but more intelligent exhibitor or attendant could have conveyed in a few words. In this respect also the members going round in a body had the advantage over the scientific tourist struggling on by himself alone.

The Exhibition is nominally an international one, but France is the only foreign country represented in the Electrical Section; and we may at once say that the representation does not do justice to French electrical engineering. Not only are the exhibits in themselves below the average in interest, but they are not properly shown. In the British Section the most striking feature is, perhaps, the very liberal way in which the Executive Council have provided space for the lighting machinery. In most previous Exhibitions the dynamos and engines for lighting were stowed away into odd spaces, and as much as possible out of sight; whereas in Edinburgh they form the principal exhibits, occupying the middle of the Machinery Hall. Another feature which could not fail to be noted by the members of the Institution as they went from stand to stand is the small extent to which the large electrical engineering firms in the South and centre of England are represented. The Exhibition is in fact principally illustrative of the work done in the North of England and in Scotland, and as such it is an admirably complete and representative show.

There is one more feature of the meeting of Electrical Engineers at Edinburgh to which we must refer; and that is the great cordiality with which the London and English members generally were received, not only by their professional brethren north of the Tweed, but by all those gentlemen who took part in organising the reception. This feeling found expression, not only in the official way by speeches and ceremonies usual on such occasions, but also in the very tangible form of an offer on the part of several prominent citizens to become the hosts to any of the members who should like to accept their hospitality during their stay in Edinburgh. We do not know to what extent, if at all, the members have availed themselves of this very liberal offer of hospitality; but the very fact that the offer was unreservedly made is a testimony of the very cordial feeling which exists between the people of Edinburgh and their scientific visitors.

THE NATIONAL TELEPHONE COMPANY.

Whatever may be thought of the future prospects of the NATIONAL TELEPHONE COMPANY, its present position, as set forth at the annual meeting last Friday, is highly satisfactory. With a dividend of six per cent., an increase in the gross revenue, a decrease in the working expenses, and a large addition to the reserve fund, the shareholders may well be content to take the good things as they come, and not inquire too curiously into the evils that may shortly be in store for them. Nor can it be said that their confidence in the present directorate has been misplaced so far. The policy of amalgamation has been steadily pursued until only two companies remain outside the National Company's system, and these will probably fall in before the next annual meeting. Similarly, the extension of the trunk lines has been courageously carried out with the object of covering the ground

Digitized by Google

and creating what the chairman called "a great stand-by in regard to competition," notwithstanding the problematical character of the profits to be derived from them. In view of possible acquisition by the State, both these projects were of doubtful expediency; but as events have turned out, the amalgamations and the trunk lines are probably the best methods that could have been devised to meet the alternative of open competition when the patent rights shall have expired. The Government having waived its right of compulsory purchase for another seven years, these precautionary measures were the only ones remaining to the companies under the circumstances.

A large portion of the Chairman's speech was devoted to the. perhaps, needless task of proving that the charges of the British Telephone Companies are not excessive when compared with those of other countries where the conditions are the same. A dividend of six per cent. is not an extravagant one; and this of itself, supposing the working expenses are not extravagant, is proof that the price demanded by the National Telephone Company for the service it renders is not unreasonably high. With the exception of Sweden and Norway, where the local conditions are peculiarly favourable to the undertakers, the charges in other European countries do not materially differ from those which obtain in this country, when allowance is made for the lines being Government property, and exempt from the royalties which British proprietors have to pay. Ten per cent. of gross revenue, on the other hand, is not an exorbitant price to pay for the privilege of pocketing six per cent. net; and it is too often forgotten that the privilege was the result of a bargain, which, had it been rejected by the Telephone Companies, would have ended their existence altogether many years ago. The price that is paid for that privilege—a very valuable one—goes into the national exchequer; and this fact has to be taken into account as a set-off, when complaints against the Company's charges assume national dimensions. But we take it that although those charges are relatively high, they are not resented so much by those who pay them as by those who are debarred from using the telephone, or by those social philosophers who argue that the popularisation of the telephone system, like the popularisation of the postal system, would work miracles for the material welfare of the people.

In this relation we may mention an interesting article which appeared in the *Nottingham Express* of 30th ult., where it was confidently argued that if the telephone were made possible of extension to every village and every market town —or, at all events, to all the outlying suburbs of large manufacturing towns—the decay of the rural districts would be arrested, and the migration of rural populations into congested centres of industry would cease. The grounds for this belief are to be found in the fact that local industry on a small scale is impossible in these days without swift means of communication with the larger centres of trade and commerce; and that a cheap and widely extended telephone system would undoubtedly supply what is needed. There are, no doubt, other causes operating to bring about the gradual extinction of suburban and rural manufactures; but it may be admitted that the one alluded to has a considerable share in the result. It is, at all events, a fresh and powerful argument in favour of the telephone service being made as popular as possible; and, of course, the propounder of this idea very much deplored the refusal of the Government to buy up the telephone interests at once. There is little doubt that this regret is widely felt; and that its acquisition by the State, with consequent popularisation of the telephone system, would have been a very welcome announcement to the community at large. Probably the chief objectors were the people at the Treasury Office, who are too much occupied at present with other schemes involving great expenditure, to entertain the idea of adding one more to the costly and gigantic businesses which the State has taken in hand.

A popular system of telephony seems, therefore, as far off as ever, for we cannot expect much in that direction from the competition with which the National Company is threatened when its patents expire. Of possible competition on the part of the Post Office the Chairman said nothing, although he was elaborate in his proofs that a projected competing company at Manchester would meet with insurmountable difficulties in its career. For our part we cannot help thinking that one of its first and chiefest difficulties will be to obtain the licence of the Postmaster-General. To grant licences to one or two competing companies would do little good, and to grant them indiscriminately would lead to nothing better than confusion all round, and render the ultimate transfer to State control more difficult than it is at present. A judicious but merciful rivalry, gradually introduced by the Post Office itself, is much to be preferred, restraining as it would do the projects of existing companies within reasonable limits, and establishing a standard of excellence and cost which the public would then have a right to expect of the Government's licensees. The significant hints he has let fall as to the impending extinction of the telephone patents indicate that Mr. RAIKES is quite alive to any advantage he may take of the changed situation which that event will bring about. Whatever may be thought of the cynical language he has employed towards them, it cannot be said that he has left the companies unwarned. His utterances indeed have been so candid that the public will require of him some corresponding action when the time for action arrives. At present they can only hope that it may be for the best interest of the public, who have a right to expect that whatever good the telephone can do, shall be done speedily, with or without the Postmaster-General's interposition.

THE EDINBURGH MEETING OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Tuesday, July 15th.

A three days' meeting of the Institution of Electrical Engineers commenced in Edinburgh on Tuesday last, the sittings being held in the Phonograph Room of the International Exhibition. About a hundred and forty members were present at the proceedings on Tuesday morning.

The PRESIDENT, in opening the meeting, expressed his satisfaction that so many members of the Institute had come to Edinburgh to enjoy the hospitality which had been so generously extended to them, to have a look round the Exhibition, which appeared to him to be of considerable magnitude and importance, to be present at the *conversazione* which was to be held that evening, and to attend the excursions that had been arranged for the visit.

The SECRETARY intimated that Sir Archibald Campbell, Bart., of Blytheswood, had sent an invitation to the Institution to visit his private workshop, in which there were many things of interest to electricians.

Papers were then read on "Some Features, mainly Electrical, of the Edinburgh Exhibition," by Dr. R. Mullineux Walmsley, and on "Foreign Currents in Telegraph and Telephone Lines," by Mr. A. R. Bennett.

In the evening the Executive Council of the Exhibition entertained the members of the Institution and a number of other guests at a *conversazione* in the Grand Hall. The company, numbering four or five hundred ladies and gentlemen, were received by Sir Thomas Clark, Chairman of the Executive,

Digitized by Google

Councillor Kinloch Anderson, Mr. A. R. Bennett, manager of the National Telephone Company of Scotland, and other members of the Executive.

Sir THOMAS CLARK having welcomed the members of the Institution to the Exhibition, Lord KINGSBURGH briefly addressed the company as a member of the Institution. Among the numerous objects of interest were phonographs, high-speed Wheatstone instruments working with Glasgow, and a line by Peterhead to Norway, by which, during the evening, Sir Thomas Clark offered the salutations of the Council to the King of Sweden, at Stockholm. The National Telephone Company had provided communication to Galashiels (40 miles) and Dundee (109 miles). Mr. Bennett exhibited some interesting radioscopes. Dr. Milne Murray showed a galvanometer for physiological purposes.

Wednesday, July 16th.

On Wednesday the meeting of the Institution was resumed in the lecture room of the Exhibition, Mr. W. H. Preece in the chair; and a Paper by Prof. W. E. Ayrton and Messrs. C. G. Lamb, E. W. Smith, and M. W. Woods, on "The Working Efficiency of Secondary Cells," was read by Mr. Lamb.

"Some of the chief Features of the Exhibition, and mainly of the Electrical Section."*

BY DR. R. MULLINEUX WALMSLEY.

After touching on the historical aspect of some of the principal exhibits, Dr. Walmsley took up the subject of telegraphy. In the modern part of an Electrical Exhibition, telegraphy, he said, naturally claimed the first place, both on account of seniority and importance. On the Post Office stand the various modern instruments now used were shown. Special interest attached to the complete set of Wheatstone fast-speed instruments, including the transmitter, the Intermediate Station or Repeater, and the receiver. There was also the ingenious Delaney distributor, by means of which six signallers could use the same line at once, or, to speak more correctly, each of the signallers in turn had the line to himself for certain fractions of each second, which follow one another so rapidly that by use of a suitable receiver at the far end the message was practically continuous. The instrument, which was of American origin, was not much used in this country, being, he was informed, only employed at present between London and Brighton, and Manchester and Liverpool. In the French Court there would be found several Baudot distributors which preceded that of Delaney in point of time, and used the same principle of two arms rotating synchronously over two discs, one at either end of the line. Of the instruments exhibited, some enabled four, others enabled six signallers to use the line.

The Eastern Telegraph Company exhibited a self-starting Morse-writer, in which the clockwork was superseded by an electro-magnetic arrangement which drove the paper by means of a pawl engaging with a toothed wheel. In connection with the exhibit of the Eastern Telegraph Company, he pointed out the electrical identity between the syphon recorder, "No. 300," and the so-called D'Arsonval galvanometer. As a matter of justice, the latter should be called either a "Thomson" galvanometer, because of the syphon recorder, or a "Maxwell" galvanometer, since its essential part figured in Clerk-Maxwell's classical book. The obvious objection of the former name was that Sir William had produced so many types of excellent current measuring instruments that the term "Thomson galvanometer" had almost ceased to have a distinct or specifying meaning. He might mention, as connected with modern telegraphy, an ingenious improvement of the Pneumatic Transmitter, exhibited by Mr. William Blakeney, of Glasgow, and called a Duplex Automatic Transmitter. The attendant had merely to place his carrier in a receptacle of the tube, and as soon as the tube was clear it would be forwarded. No complicated system of levers had to be worked, nor had any signal to be sent between the attendants at the two ends. That was accomplished by means of electro-magnets and a simple reversing key.

Dealing with electric lighting, he said the actual lighting of the Exhibition did not offer any particularly novel feature. The arc lighting was in charge of the Brush Electrical Engineering Company, who used their well-known double carbon 10-ampere lamps. The bulk of the glow lighting had been carried out by King, Brown, and Co. The only purely American lighting exhibit was a 30-arc light dynamo, together with 30 arc lamps of the Western Electric Company, of Chicago. Visitors would, he thought, be interested if they would compare various details connected with that machine with English built machines. The lamp was a well-made and simple clutch lamp. Perhaps the only point about its mechanism was the very small amount of travel and the strong pull required on the armature of the series magnet to strike the arc. It was fed with a current of 18 amperes at 30 volts; in other words, the arc was deliberately intended to hiss, a method which would scarcely find favour on this side of the ocean.

With regard to prime movers, he drew attention to the vertical Compound engine exhibited by the Brush Company. Special engines for electric light work were exhibited by Mr. David Carlaw, of Glasgow, and Messrs. J. F. Blyth and Co., who manufacture the "Newall" engine (see *Electrician*, December 27, p. 196). All the well-known gas engine makers were represented. With the amount of water power that was available in Scotland it was surprising that so few water motors were exhibited. A good collection of "Waverley" turbines was shown by Messrs. Carrick and Ritchie. The sizes ranged from 2·7 to 105 horse-power for falls varying from five to 80 feet, and a large proportion of the available energy was given out on the shaft. In regard to the transmission of power, he pointed out that the electric launches plying on the canal only differed from those used on the Thames in one or two unimportant details. The other chief working examples of the electric transmission of power were the Telpher line and the Electric railway.

The telephone exhibits did not offer many striking novelties for comment. The visitor could, within a small compass, compare the instruments produced under the close monopoly which prevailed in this country with those which were the outcome of the competition between the various French firms. An ingenious automatic switch-board, with transmitter, receiver, &c., was shown by the Consolidated Telephone Construction Company (see *Electrician*, Feb. 14, p. 370). It should be of great service to hotels, works, warehouses, &c., which required the use of several telephones without the expense of an exchange installation. The National Telephone Company also displayed a few exhibits, amongst which was a Bennett's telephonic transformer or translator. This exhibit was very interesting from the fact that a closed magnetic circuit was used, and was found in practice to be better than an open circuit; it could be used both to ring up and to talk through, whereas, the older forms were not applicable to both purposes. As regarded long-distance telephones, some of the visitors might be interested to hear that they could talk through from the Exhibition to Aberdeen, a distance of 200 miles, also to Hawick in the south, and to Glasgow, Ayr and Greenock in the west. In fact, the network of trunk lines for central Scotland was fairly complete.

Although he had not room in his Paper to refer to the various purposes for which electric signalling was employed as distinct from the interchange of correspondence or telegraphy, he informed those interested in that important branch of electrical development that they would find in the Exhibition good exhibits of the most recent devices in actual operation. He might, perhaps, specially direct attention to the exhibits of the London and North-Western Railway Company, the Eastern Telegraph Company, Messrs. Woodhouse and Rawson, and Messrs. Cox-Walker and Co.

DISCUSSION.

The CHAIRMAN, having proposed a vote of thanks to Dr. Walmsley for his interesting Paper,

Mr. A. R. BENNETT said he was sure that after the description Dr. Walmsley had given of the electric tramway, it would be heard with a feeling of regret that that tramway was not yet open. The author had referred to "Bennett's translator," upon which he wished to make a remark. The original translator was his own, but the improvement which consisted in the close magnetic circuit was not his. It was a great improvement, but he was not aware who was responsible for it. With these, subscribers could ring through from one end to another.

Mr. W. H. PREECE expressed the thanks of the Council to Dr. Walmsley for his Paper. He should like to supply the Doctor with the accurate number of circuits of Delaney's multiplex apparatus. He could not make out more than sixteen circuits from memory; but he was very proud to know that these sixteen circuits were at work. This was an apparatus he saw at an exhibition such as this in 1884 in Philadelphia. It did not there attract much attention, but he saw it contained immense merit, great novelty, and solved in particular the problem of multiplex telegraphy. He induced Delaney to bring it over to the Inventions Exhibition for the next year. They tried it in the Post Office and found it work well. It was really now a practical instrument, and they had not used it yet in America.

Mr. C. E. SPAGNOLETTI said he wanted to add a few remarks to Dr. Walmsley's description of the long-distance telephones because he had an opportunity of being introduced to the gentleman who brought over the long-distance telephone. They tried some experiments with this instrument and made a communication with Reading on the Great Western Railway to Weymouth by one route and back another, a distance of about 470 miles, and they heard very well indeed. The Telephone Company then thought they would try the Bell telephone against this, and the result was that it was almost better than with the long-distance instrument. They tried it again from Victoria Station to Dover, communicating between two rooms in the station which was a distance of 300 miles. The conversation was heard very distinctly. He thought Mr. Preece had told them this

* Abstract of Paper read at the Extraordinary General Meeting of the Institution of Electrical Engineers, Edinburgh, 1890.

Digitized by Google

had been beaten, because by a cable they had succeeded in communicating a distance of 1,000 miles.

Mr. PREECE said he had been wondering how, why, or where Mr. Spagnoletti had derived information from him that it was possible to speak through a thousand miles of cable; but he remembered it had been announced that they had spoken through a thousand miles of cable coiled in tanks at Henley's Works. There was a new telephone being shown that was said to speak through a thousand miles of cable, and there was no doubt if one put himself at each end of the cable, it did speak beautifully. But when he suggested that a telephone should be put half way nothing would be heard. It was, as Mr. Bennett had said, merely an electrostatic action at the ends of the wire. This was a fallacy that had been very often repeated, and he was sorry to say he had been compelled to arrange for experiments along two actual cables in the North Sea, from Holland to England, in order to convince certain gentlemen that it was impossible to speak through such a long distance. It was perfectly easy to speak a thousand miles or more on overhead wires, and it was just as easy to construct a line of two wires to speak between London and Edinburgh as between Edinburgh and Glasgow.

Dr. WALMSLEY returned thanks, and expressed on behalf of himself and Mr. Bennett their readiness to undertake the guidance of the party through the Exhibition.

THE WORKING EFFICIENCY OF SECONDARY CELLS.*

By W. E. AYRTON, C. G. LAMB, E. W. SMITH, and M. W. WOODS, Associates.

1.—*Previous Tests of Cells.*

Since 1881, when the formation of Planté storage cells was greatly accelerated by Faure's device of pasting the plates, numerous tests have been made in different parts of the world on the capacity and efficiency of secondary cells. The first tests that were carried out were conducted simultaneously, at the end of 1881, in England by Prof. Perry, with one of the authors of this paper, and in France by a committee consisting of Messieurs Tresca, Potier, Joubert, and Allard, working at the Conservatoire des Arts at Metiers, with a staff of assistants.

In the report—communicated to the Physical Society in February, 1882—by the two English experimenters, it was pointed out that the great "resuscitating power" of the cells made it very difficult to say when they were entirely discharged, and therefore, in order to test the efficiency, the cells were first "emptied" of charge by discharging them until the discharge current was very small, and finally leaving them short-circuited for many hours with a short bit of thick wire. Next, a measured amount of energy was put into these "empty" cells, and they were then thoroughly discharged on three successive days, being insulated and allowed to recuperate during the two intervening nights. Although the energy efficiency thus obtained, and which was not less than 82 per cent., probably represented much more than could be obtained in practice at that period, if the discharge were stopped before the E.M.F. fell to so low a value, this efficiency represented something quite definite, since all the energy given out by the cells in the discharge must have been put into them during the measured charge, no demand being made on some inexhausted store of energy previously put into the cells.

The French Committee, on the other hand, considered the cells as being discharged when a certain current which was originally produced through a fixed resistance by 30 cells could no longer be kept up, even when the number of cells had been increased to 35. But unless, subsequently to the receipt of the cells from the manufacturers, they had been charged and discharged several times until the same cycles of values of E.M.F. with time were repeated with each charge and discharge, there was no guarantee that in the experimental discharge the cells were not drawing on a store of energy put into them before leaving the manufacturers' premises, and thus giving a higher value than the "working efficiency."

And we are afraid that a very possible neglect of the powerful resuscitating power of accumulators may have vitiated some of the published results of experiments that have been made on them. This doubt must not be forgotten in considering the list on opposite page, which is as complete as we have been able to make it, of all such experiments that have been made up to date. At the middle of 1889, when we had nearly completed our investigation, there appeared two very important contributions to the subject—one on "The Inherent Defects of Secondary Batteries," by Dr. Louis Duncan and H. Wiegand; the other, "Ergebnisse von Versuchen an Akkumulatoren für Stationsbetrieb" by Professor W. Kohlrausch and C. Heim. These investigations are extremely interesting, as they confirm some of the results which we had also arrived at, and to which reference will be made in this Paper;

* Read at the Extraordinary General Meeting of the Institution of Electrical Engineers at Edinburgh, on July 16th, 1890.

Professor W. Kohlrausch and C. Heim, for example, laying great stress on the fact that the discharge of an accumulator does not depend merely on the previous charge, but on the previous history of the cell.

At the Central Institution there are three distinct types of E.P.S. cells in daily use. The cells, however, used by us for the investigation were 20 out of a group of 50 of what is known as the 1888 type. This type we selected, since it was the latest constructed by the Electrical Power Storage Company. The particular specimens of this 1888 type, which are at the Central Institution, contain each two positive and three negative plates, each plate, exclusive of the lugs, being 9¼ by 9¼ inches. The glass vessels containing these plates are large enough to each hold 7L plates, but we preferred to use 7L glass boxes to having smaller boxes specially constructed.

The total weight of each of these cells is about 59 lbs. 12 oz., made up as follows:—

	lbs.	oz.
3 negative plates	about 17	2
2 positive ,, ...	,, 11	8
Ebonite strips.....	,, 0	8
1 glass vessel	,, 7	8
Dilute sulphuric acid.....	,, 23	2

and the cells are intended to be used with a maximum current of 9 amperes on charging and 10 on discharging.

The first point to settle with reference to the discharge was whether the resistance in the circuit should be kept constant, or whether as the E.M.F. fell the resistance should be varied in such a way as to keep the current constant. This latter method, although it involved much more labour, was adopted. At first the current was kept constant by varying the resistance by hand

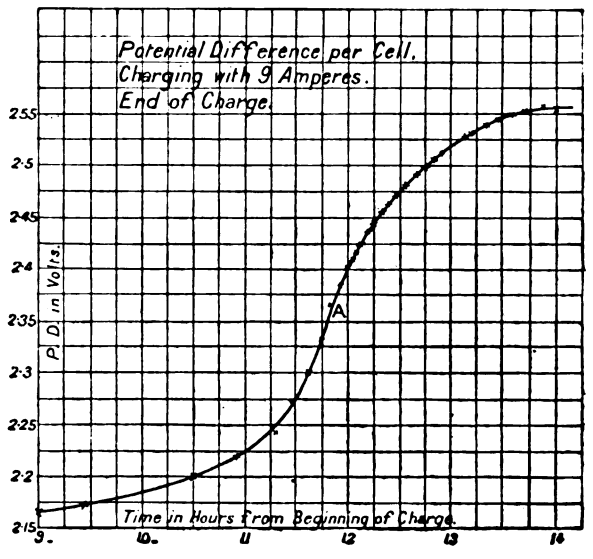

FIG. 1.

as the E.M.F. of the cells altered. But this required the constant presence of one of the observers day and night, partly to vary the resistance from time to time, and partly to start the charging directly the discharging was finished, in order that the cells might never be left discharged. Hence an automatic arrangement, which will be described later on, was subsequently devised, and by means of it the current was maintained more constant than could be achieved by even very careful hand regulation, and the circuit broken during discharging and during charging the moment the potential difference reached certain pre-arranged values.

We had next to adopt a criterion by which to settle when a charge or discharge could be said to be completed. Such a criterion may be made to depend on a variety of changes that take place in a cell, three of which are in common use—viz., change in the specific gravity, gassing, and change in the potential difference. In the case of the cells tested by us, and which have more liquid in proportion to the plates than is usually the case, the change in specific gravity from charge to discharge is from 1·2 to about 1·17: and, as our experiments show that the change is directly proportional to the time, when the current is kept constant, the change in the specific gravity per hour is only about 0·002, which is far too small to be read very accurately with ordinary hydrometers. But it is known the fall in the E.M.F of the cells at the end of the discharge is very rapid, so that half-an-hour more or less in the time of the discharge produces a great difference in the value of the E.M.F.; hence it follows that, if a specific gravity test were alone employed with our cells as a criterion of charge and discharge,

	„	„ „	90	80	Cells first completely discharged by the external resistance being gradually diminished to nought
					The positive plates of these Tudor cells are first formed by Planté's process, then the holes in the grids are filled with minium, and the forming continued. The negative grids are not formed at all, but merely have the holes in the grids filled with lead oxide.

it would be necessary to read the specific gravity accurately to less than 0·001 at the end of the discharge. The amount of gassing is also far too rough a test, and cannot be employed at all in the discharge, hence we were led to resort to the variation in the potential difference.

A number of experiments were now made on two of the cells in order that the *exact* shape of the curves of potential difference at the *end* of the charge and discharge might be ascertained. The curve shown in Fig. 1 is the end of the potential difference curve for one cell on charging with 9 amperes for 14 hours; from which we see that the rate of variation of the potential difference

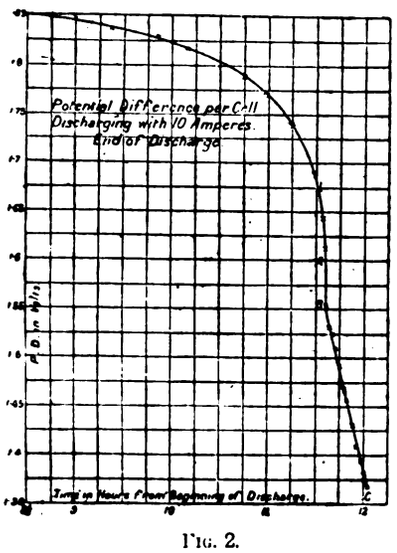

Fig. 2.

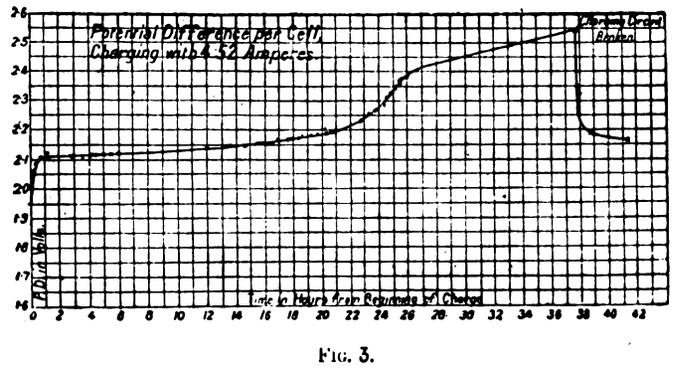
with time is greatest when the potential difference is about 2·36 volts, indicated by the point A. In Fig. 2 is shown the curve of potential difference during the last 3½ hours of a discharge with 10 amperes, the discharge being continued for 12 hours. In this particular experiment the discharge was allowed to continue until the potential difference fell to 1·365 volts, indicated by the point C, which is far lower than we have dared on any other occasion to allow the potential difference to fall. At about 1·8 volts the potential difference curve begins to fall pretty rapidly, and the slope of the curve, or the rate of diminution of the potential difference with time, goes on increasing until the potential difference has fallen to 1·6 volts, indicated by the point A on the curve in Fig. 2. Here $\frac{dV}{dt}$ per cell has reached a value 1·4, V being measured in volts and t in hours. Below this the curve has a shape that has not hitherto been noticed, for when the potential difference per cell has reached 1·556 volts, indicated by the point B, the curve suddenly alters its shape, becoming the straight line B C, with a less inclination to the axis of time, $\frac{dV}{dt}$ being for this line only 0·44.

Just as we have in the curve in Fig. 2 continued the discharge much below the usual limit, so we examined what would take place if the charging was also prolonged much beyond the usual limit. Curve 3 shows the rise of the potential difference when the charging at 4·52 amperes was continued for 37½ hours, 25½ hours being sufficient to fully charge the cells with this constant current of 4·52 amperes—that is, to charge them until the potential difference per cell was 2·4 volts. It will be observed that whereas the volts rise from 2·25 to 2·38 between 23·1 and 25·5 hours—that is, 0·13 volt per cell in 2·4 hours—the rise in the following 12·3 hours is only from 2·38 to 2·55 volts: this is only 0·17 volt. The continuation of the curve shows the drop of potential difference on breaking the charging circuit; there is an instantaneous fall of 0·28 volt per cell, and a further fall of 0·1 volt in the E.M.F. in two hours.



Potential Difference per Cell,
Charging with 4·52 Amperes.
Charging Circuit Broken.
Time in Hours from Beginning of Charge.

Fig. 3.

The curve on Fig. 4 shows on a larger scale this drop on breaking the charging circuit when the cells are very well charged, leaving it broken for five minutes, and then closing it again, the charging current in this experiment being 9 amperes. There is, we see, a nearly instantaneous drop of the terminal potential difference per cell from 2·56 to 2·31, then a steady fall in the E.M.F. from 2·31 to 2·24 volts in five minutes. On reclosing the charging circuit at this moment, there is an instantaneous rise of the potential difference to 2·48 volts, and then a slow rise to 2·56 volts in five minutes; so that after reclosing the charging circuit it took, in this experiment, the same time for the potential difference to recover the value it had just before breaking as the time during which the circuit remained broken.

Experiments were also made on the time rise of the E.M.F. on stopping the discharge. Later on, however, the time rise of the E.M.F. on breaking the discharge circuit, as well as the time fall of the E.M.F. on breaking the charging circuit, for various currents,

Digitized by Google

was measured in a far more sensitive way than in the early part of this investigation; this subject, will, therefore, be left until further on in this Paper.

On starting a discharge the potential difference generally falls slightly to the value that is maintained fairly constantly during a long portion of a discharge. After a prolonged rest, however, we have found that the potential difference, on the contrary, shows a *decided rise* at the commencement of a discharge, and that it is not until the third discharge takes place that the curve resumes its normal character with the slight drop in the value of the potential difference at the commencement of the discharge.

II.—*Efficiency.*

In the earlier of the experiments made by us on the efficiency, two distinct groups, each of 10 cells, were employed. The current passing through the two sets of cells also passed through two platinoid strips, and the potential difference at the terminals of each of these platinoid strips was measured by a suitable low-resistance galvanometer, whose indications, therefore, measured the respective currents passing through the two sets of cells. The potential difference at the terminals of either group of cells was measured by means of a high-resistance D'Arsonal galvanometer, which by means of a switch could be connected with the terminals of either of the two groups. The high-resistance and one of the low-resistance instruments have been absolutely calibrated very frequently during the past few years, by means of the silver voltameter, known resistances, and Latimer-Clark standard cells. A special calibration was also taken of these instruments, both just before these experiments were commenced and at their conclusion.

Group No. I. of 10 cells was first charged with 9·05 amperes and discharged with 9·933 amperes, there being four discharges alternated with four charges, without intermission from January 8th to January 12th, 1889, both days inclusive. One of the observers was always present (day and night) to keep the current constant by hand regulation, to take frequent readings of the

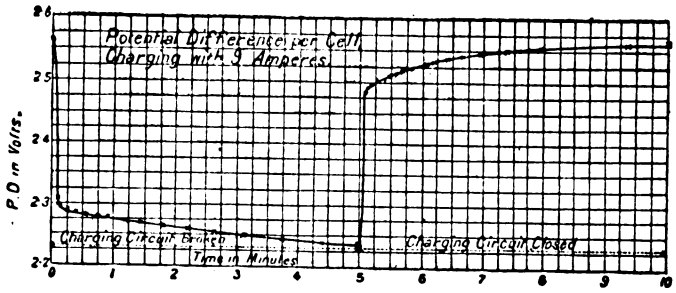


FIG. 4.

potential difference at the terminals of the set of 10 cells, to stop the charging when the potential difference per cell reached 2·4 volts, and immediately start the discharging, as well as to stop the discharging when the potential difference per cell reached 1·6 volts and instantly start the charging again so that the cells were never left discharged.

We used the limits 2·4 and 1·6 volts per cell as the criterions for stopping respectively the charge and discharge, since, as already seen, the slope of the charge and of the discharge curves are greatest for about these values of the potential difference.

Next, Group I. was charged with 4·519 amperes and discharged with 9,933 amperes, twice, without intermission, from January 14th to January 19th, inclusive, the potential difference limit for charge being 2·4 volts, and for discharge 1·5.

And while the two sets of tests were being made with Group I., Group II. was first charged with 9·104 amperes and discharged with 4·858, twice, without intermission, from January 9th to January 12th. And, lastly, Group II. was charged with 4·519 amperes and discharged with 4·858, without intermission, from January 14th to January 19th, both days inclusive.

Shortly, then, the tests were :—

	Charge.	Discharge.	
Group I.	9	10	amperes.
	4½	10	„
Group II.	9	5	„
	4½	5	„

The coarse adjustment of the resistance for keeping the current constant was effected by means of resistance coils made of bare German silver wire suitable for standing large currents. The fine adjustment was performed by means of horizontal mercury troughs through which the current passed, the lengths of the mercury in the wooden troughs through which the current passed being varied by copper bridge-pieces. This mercury trough arrangement forms an extremely convenient resistance for delicate adjustment by hand. To keep the current as constant as possible a dynamo was not used to charge the accumulators under test, but they were charged instead from other accumulators of much greater storage capacity.

The general expressions for the ampere-hours and watt-hours given out by an accumulator are, of course,

$$\int_0^{t_1} A_1\,dt, \text{ and } \int_0^{t_1} V_1 A_1\,dt,$$

where A_1 and V_1 are the current in amperes passing through the accumulator, and the potential difference at its terminals at any moment, and t_1 is the time in hours during which the discharge lasts. Consequently, if A_2, V_2, and t_2 have similar meanings for the charge, the complete expressions for the quantity and energy efficiency are, respectively,

$$\int_0^{t_1} A_1\,dt \div \int_0^{t_2} A_2\,dt,$$

and

$$\int_0^{t_1} V_1 A_1\,dt \div \int_0^{t_2} V_2 A_2\,dt,$$

In our experiment A_1 has a constant value during the discharge, and A_2 a constant value during the charge, so that the expressions for the quantity and energy efficiency reduce themselves to

$$\frac{A_1 t_1}{A_2 t_2}, \text{ which is very easy to calculate,}$$

and

$$A_1 \int_0^{t_1} V_1\,dt \div A_2 \int_0^{t_2} V_2\,dt.$$

To obtain $\int_0^{t_1} V_1\,dt$ a time curve of the values of V_1 is drawn and integrated; similarly, to obtain $\int_0^{t_2} V_2\,dt$ a time curve is drawn for V_2 and integrated; then, multiplying the first integral by the steady value of the discharge current A_1, and the second integral by the steady value of the charge current A_2, we have, respectively, the watt-hours given out in the discharge and the watt-hours put into the accumulators in the charge.

After drawing a series of time curves for the potential difference in the various experiments already referred to, and integrating them with an Amsler's integrator, we obtained the following results for the successive charges and discharges :—

Group of 10 *Cells.—No.* I.

Discharge at 9·933 amperes.		Charge at 9·05 amperes.		Percentage.	
Ampere-hours.	Watt-hours.	Ampere-hours.	Watt-hours.	Quantity efficiency.	Energy efficiency.
119	2,280	114	2,435	105	94
105	2,045	102	2,220	103	92
101	1,970	101	2,220	100	87
104	2,020	104	2,270	100	89
Discharge at 9·933 amperes.		Charge at 4·519 amperes.			
112·5	2,170	115	2,485	98	87
113	2,190	115	2,485	98	88

Group of 10 *Cells.—No.* II.

Discharge at 4·858 amperes.		Charge at 9·104 amperes.		Percentage.	
Ampere-hours.	Watt-hours.	Ampere hours.	Watt-hours.	Quantity efficiency.	Energy efficiency.
144·5	3,055	138·5	2,910	111·5	103
141·5	2,770	129·7	2,820	109	98
Discharge at 4·858 amperes.		Charge at 4·519 amperes.			
143	2,785	141	3,075	102	90·5

Now, not only are quantity efficiencies of 105, 103, 111, 109, &c., per cent. impossible, but energy efficiencies of 94, 92 per cent. are also too high, when accumulators are being charged and discharged at the maximum rate allowed by the manufacturers. Further, it is noticeable that for each set of tests both the quantity and energy efficiencies diminish on the whole as the tests proceed. These cells, like the other cells in the Central Institution laboratories, have

Digitized by Google

been charged at regular times ; and as the number of ampere-hours taken out of them for ordinary laboratory work varies very much, the intervals between the periodic chargings are so arranged that on the whole the cells are charged up much more than they are discharged.

Hence, at the commencement of these tests the cells had a large store of energy in them on which to draw in the discharges, the results of which are given in the preceding table. From this we learn this very important fact—that *if accumulators be thoroughly well charged up before being tested, then five days' continuous charging and discharging alternately with even the maximum currents allowed by the manufacturers fails to give the normal quantity, or energy, efficiency.*

It will be noticed that both the ampere-hours and the watt-hours are increased by diminishing the current employed. This is partly due to the fact that if a fixed potential difference limit per cell be employed either in discharging or charging, the cell is discharged until the E.M.F. is slightly lower, and charged until the E.M.F. is slightly higher for a small current than for a larger one.

(To be continued.)

LEGAL INTELLIGENCE.

King, Brown, and Co., v. The Anglo-American Brush Electric Light Corporation.

JUDGMENT.

The First Division of the Court of Session (the Lord President and Lords Adam and McLaren on the bench) gave judgment on Wednesday in the action by King, Brown, and Co., Edinburgh, to reduce the patent No. 2,003 of 1878 of the Brush Corporation for compound-wound dynamo machines. A long proof was led in the Outer House before Lord Trayner, who thereafter reduced Brush's patent on the ground that it had been anticipated by Varley's patent, No. 4,905 of 1876, both by prior publication and by prior use. Against this judgment the Brush Corporation reclaimed to the First Division ; and the case was debated some weeks ago.

The Division adhered to the judgment of the Lord Ordinary.

LORD McLAREN, who read the judgment of the Court, said : The defenders, the Brush Electric Light Corporation, claim under their patent the exclusive privilege of making dynamo-electric machines in which the electro-magnets are of the type known as "compound-wound." The pursuers, King, Brown, and Co., are makers of "compound-wound" dynamos ; and their right to make such machines having been extra-judicially challenged, they have brought this action to have the defender's patent reduced and declared void on various grounds : the chief objection being that the invention of compound-winding was previously discovered and made known by Mr. Varley, and consequently that Mr. Brush or his assignees are not in the position of being the "first and true inventors" of this valuable electric appliance. There can be no doubt that the holder of Brush's patent claim compound-winding as an essential feature of their machine, and accordingly if this claim be ill-founded the patent must fall. The argument was directed mainly to the question of the anticipation of the Brush system of compound-winding by Mr. Varley ; and I shall consider this subject in the first place, touching afterwards on the objections to Brush's specification, which are of a technical character.

In order to make my observations intelligible, I must begin by stating in what compound-winding consists. In the rudimentary form of the dynamo-machine I understand that the excitation of the electro-magnets was maintained from a separate, or as it is termed an external source, generally a battery of some kind. The first improvement consisted in winding one of the conducting wires round the electro-magnets, the continuation of this wire being led into the external or working circuit. In this way the current flowing from the dynamo was made to maintain the magnetism of the electro-magnets as a part of the work which it had to perform. This is known as series-winding. The next improvement consisted in dividing the current as it flowed from the commutators into two partial currents. In this system the wire is bifurcated ; one branch is wound round the electro-magnets and is returned to the opposite poles of the commutator. The second branch wire is employed for lighting or external work of some kind, and is remitted to the first branch wire near where it meets the commutator at the opposite pole. This is the form known as shunt machine. The invention of compound-winding, with which we are here concerned, consists in, I will not say a combination of the two methods ; but with the addition of the shunt and the series method. The wire is divided or bifurcated as it leaves the commutator. Both the branches are wound round the electro-magnets. One of these is directly returned to the opposite pole of the commutator without doing any work other than the excitation of the magnets. The second wire on leaving the electro-magnets is continued to form the external or working circuit, and is ultimately re-united to the first wire. This arrangement seems to be an exception to the rule against trying to do two things at the same time : because it is admitted that the compound-wound machine is a much better working machine than the shunt. It appears that the sections of the wire can be so proportioned that a nearly uniform current flows in the working field, notwithstanding variations in the quantity of work to be done. It is not necessary for the purpose of the case to explain why this should be ; and, if it were necessary, I am not sure that I am able to explain it. It is a question of the mathematical theory of current-electricity. But it is agreed that the compound wound machine, when the wires have the proper relative conducting capacity, gives better results as regards uniformity and steadiness of the current than are attained by either the series or the shunt ; and this explains the importance of the right to use this invention to the parties concerned.

I may here observe, it is not clear to me that either Varley or Brush were at first fully aware of the scientific and practical importance of the principles of compound-winding. Varley was the inventor, or one of the inventors, of the "series" machine ; and both Varley and Brush were doubtless, aware of the advantages and disadvantages of the "series" and the "shunt." The idea of introducing the two methods into the same machine is one that would very naturally occur to any one familiar with the subject and practically conversant with dynamo machines. Assuming that this is intelligently done, with the object of getting a better working machine through the union of the series and the shunt than is attainable by either of these modes of winding singly, then the invention is a proper subject of a patent, and it is not necessary to its validity that the patentee should have foreseen all these advantages which have been realised through a subsequent introduction of electric lighting with the incandescent lamp. I may also observe that in Brush's specification, as well as in Varley's specification, the mode of winding is only treated as one among many other parts of a dynamo-machine ; and it is quite possible that a reader, even if conversant with the subject, might peruse either of these documents without having his attention specially called to the novelty of the system of compound winding. But neither will this consideration affect the question. An inventor may describe his invention clearly without proclaiming it as a very important discovery, and the question is whether compound winding is clearly described in Varley's specification.

The specification in question is No. 4,905 of 1876, and its title is "Improvements in apparatus for producing the electric light, parts of which invention are applicable to other purposes." The alleged anticipation is contained in the two paragraphs, page 4, lines 11 to 21 :—"Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light." I interrupt the reading to remark that, in the words I have read, the writer only announces what he is going to do, and does not profess to be explaining his method. This obvious and I should have thought superfluous criticism disposes of many pages of evidence in which witnesses are brought to say that these words would not give them a clear idea of the method of winding. The specification proceeds :—"There are several well-known ways of doing this" (that is of diverting a part of the electric energy developed by the machine) ; "but the method I prefer is to wrap the soft iron magnets with two insulating wires, one having a larger resistance than the other. The circuit of larger resistance is always closed, and the circuit of less resistance is used for the electric light." If the description had stopped here, I should not have doubted that it contained a clear description of the *construction* of a compound-wound machine. I mean a description of so much of the apparatus as is included in the name compound-winding. The direction is to wrap the magnets with two insulating wires ; it is, of course, implied that these wires are to carry currents coming from the machine ; but this is not left to implication, because it is clearly explained that these insulating wires are the media for the transmission of separate currents, the one of larger resistance being always closed (in other words, acting as a shunt), while the other is used for the electric light (having previously contributed to the magnetisation of the magnets by being wrapped around them). But if the description had stopped here, it would have been open to the observation that while it described the construction it did not indicate, except in a very general way, the use of the compound machine of the magnets. Now I could hardly consider that to be an adequate description of an invention which should leave the reader in ignorance of its utility and its mode of action. But the information which I desiderate is supplied by the second paragraph : "When the electric light is being produced the greater portion of electricity passes through the circuit of less resistance, which I term the 'electric light circuit,' maintaining the magnetism of the magnets and producing the light. When the electric light circuit is open from any cause the electricity developed passes through the circuit of greater resistance only and maintains the magnetism of the magnets." There is here plainly described one of the advantages of the compound-wound dynamo, probably the only one known to the writer, viz., that when work is being done in the external circuit, the magnets have the benefit of the unobstructed flow of the electric current through the wire of larger resistance and less resistance, while when the external circuit is open and no work is being done, the magnets receive through the wires of greater resistance the current which is sufficient for their excitation. I am here merely paraphrasing Mr. Varley's description without meaning to add anything to it ; and I think that anyone conversant with the subject, and reading this paragraph (whether he agreed with Mr. Varley or differed with him as to the possible benefits to be attained), would not be left in doubt as to what Mr. Varley considered to be the *rationale*, and the mode of action of the arrangement of wires described in the preceding sentences.

I have difficulty in understanding how it is that a considerable number of able and distinguished men should have been persuaded to give their evidence as to the alleged insufficiency of Mr. Varley's description as an anticipation. To a considerable extent the evidence of the witnesses of the Brush Company is made up of somewhat minute and verbal criticism on the expressions used by Mr. Varley ; but, in so far as these gentlemen indicate an opinion as to the insufficiency of the description in its entirety, I think their conclusions are in part explained by their having misapprehended the question ; because I observe that the question is frequently asked and answered whether Varley's specification is such as

Digitized by Google

would enable an ordinary workman to make a compound-wound machine. Now, the question of anticipation does not depend (in our opinion) upon that test. We are not here trying the sufficiency of Varley's specification as a specification. Varley is not here claiming any exclusive privilege (his patent has long since expired); and we have no occasion to consider whether he fulfilled the duty which is the counterpart of the exclusive privilege given to a patentee of particularly describing and ascertaining the nature of his invention and the manner in which it is to be performed. I am very far from saying that Varley's specification is insufficient as a specification of a patented invention. I rather think it would be held to meet the requirements of the statute of King James. But the question we are now considering is quite different; it is whether Mr. Brush is or is not the first and true inventor of compound-winding, and the negative of that proposition may be proved by showing that the invention was previously described, not necessarily in language sufficient as a direction to a mechanic, but in language clear and intelligible to educated men conversant with the subject, and capable of giving the necessary directions to the hypothetical workman. An invention may be clearly described in mathematical or chemical symbols, the latter being perhaps the preferable illustration. Such a description, although it may have to be translated for the instruction of the operative chemist (just as if it were written in a foreign language) would be an anticipation of the same invention described in popular language, such as is required (as far as practicable) by our Patent Law. Now, I venture to think that if Varley's description had been put into the hands of any of the defenders' witnesses (without reference to any question under the Patent Laws) that he would have understood it, and would have been able to instruct a workman to make an experimental machine. I think I can collect from their evidence that the witnesses on both sides understood the specification perfectly, although some of them were certainly apprehensive that other persons less gifted would not find it so easy to be understood.

It is a remarkable circumstance in this case that neither in the course of the trial nor in the argument addressed to us has any reference been made to Brush's description of compound-winding. It seems to have been assumed that it at least was a pattern of clearness, and certainly no objection was taken to it on the ground of insufficiency. Brush's description is contained in the following passage in his specification:—"In applying my invention to dynamo-electric machines, I wind the cores of the field-magnets with a suitable quantity of a comparatively fine wire, having a high resistance in comparison with that of the external circuit and the rest of the wire in the machine. The ends of this wire are so connected with the other parts of the machine that, when the latter is running, a current of electricity constantly circulates in said wire, whether the external circuit be closed or not. The high resistance of this wire prevents the passage through it of more than a small proportion of the whole current capable of being evolved by the machine; therefore, the available external current is not materially lessened. When this device, which I have called a 'teaser,' is used in connection with field-magnets, also wound with coarse wire, for the purpose of still further increasing the magnetic field by employing the main current for this purpose in the usual manner, then the 'teaser' may be so arranged that the current which passes through it will also circulate in the coarse wire, thus increasing the efficiency of the device." Now if Varley's description be insufficient, I do not see how the validity of Brush's patent can be maintained, because the two descriptions are practically identical. Conversely, if the invention of compound winding be well described in Brush's specification, the identical description in Varley's specification must be an anticipation. I do not mean, of course, that the language of the two descriptions is absolutely identical. In describing the shunt arrangement, Brush calls it a "teaser" (I do not know whether electricians attach any significance to this vocable), and there are some other variations of expression. But I can find nothing of substance in Brush that is not in Varley, and I cannot help adding that if there be any difference, Varley's description is the more easily understood of the two. This completes what I have to say on the subject of anticipation by prior publication.

There is also a plea of anticipation by prior use. On this point the facts are these:—In the interval between the filing of the provisional and complete specifications, Mr. Varley had a machine made to his direction by the firm of Siebe and Gorman. When the machine was first tried it did not work well, because its frame was not sufficiently strong to prevent the revolving armature being attracted into contact with the electro-magnets. I need not say that the motion of the armature must not be resisted by friction, but only by the immaterial though not less real resistance offered by the forces developed in the magnetic field. This was corrected by strengthening the frame, and the machine was successfully used in the production of an arc light by the lamp produced along with the machine. Siebe and Gorman are makers of diving apparatus, and the lamp was used on their premises to exhibit the apparatus under water in a tank which they had for the purpose. The case on public use is narrow; but we consider that what I have described is public use as interpreted by decisions. The machine in question was produced, and it is a compound machine; nobody has said anything to the contrary, though some of the defenders' witnesses say that if the wires were uncoupled, or were coupled up in a different way, it would no longer be so. But the effect of uncoupling the shunt wires would be to render this part of the winding simply useless for any purpose, as would indeed be the case with a machine of any kind if a material part of the mechanism is put out of its place or turned the wrong way. The Lord Ordinary has in his judgment extracted some of the more noticeable expressions of opinion by the scientific witnesses on the questions of prior publication and prior use, and has pointed out the insufficiency of the reasons given for holding Varley's specification to be incorrect or incomplete. I concur in the Lord Ordinary's view as to the weight to be attached to this part of the evidence, and in his lordship's opinion generally on the facts of the case, except in so far as he may be held to imply that the test of the sufficiency of an anticipation is the same as the test that would be applied to the construction of a specification founded on as such.

There is another objection to the defender's patent, and it is founded on an alleged inconsistency between the provisional and the complete specifications. The provisional specification announces as one of the improvements for which the patent is granted an improved construction of the commutator. The function of the commutator is to convert the alternating currents (as they pass from the revolving axis to the external circuit) into one continuous current. This is accomplished by fitting the axis in insulated segments, to which the poles of the armature are connected by insulated wires, and these segments are so arranged that at the moment when the current in the machine is reversed, the external wire becomes disconnected from the corresponding segment, and is at the same time brought into connection with the segment which is attached to the opposite pole of the armature. The improvement indicated in the provisional specification is a purely mechanical improvement for the purpose of obtaining a mechanical advantage. But, in the course of perfecting his invention, Mr. Brush found that an electrical advantage might also be secured by means of a slight variation of the mechanical arrangement indicated in the provisional specification. The variation consists in separating the segments; so that, for a small fraction of each semi-revolution, the current shall be interrupted; that is to say, the current is cut off during the brief interval when the armature (or the particular member of the compound armature) is in a neutral position, and when the resultant of the forces acting on it is therefore very small. In the complete specification, the variation whereby this electrical advantage may be gained is claimed as one of the patented improvements; and the question arises whether this difference between the provisional and complete specification does not exceed the latitude allowed to an inventor who is only perfecting what he has provisionally announced. The Lord Ordinary has held that the claim referred to is not covered by the provisional specification, on the ground that, although the construction of the commutator as perfected is not materially varied, yet as the variation represents a distinct principle and is directed to an object distinct from that which is indicated in the provisional specification, the two things cannot be regarded as identical inventions. There is much force in the Lord Ordinary's view on this question; but we consider it unnecessary to come to a decision upon it, because we are all of opinion that if there had been no more serious objection to the Brush patent than this, it would be only fair to the patentee that he should be allowed an opportunity of disclaiming this variation on one of the patented improvements. But this is not the condition of the case as it arises for decision, because we are agreed that the patent is invalidated in its essential and fundamental principle by reason of the prior publication and prior use by Varley of the invention of compound-winding, for which this exclusive privilege is given. For these reasons I am of opinion that the interlocutor of the Lord Ordinary should be adhered to, and decree of reduction of the patent pronounced.

The LORD PRESIDENT: That is the opinion of the Court.

On the motion of Mr. DANIELL, counsel for King, Brown, and Co., the Brush Corporation were found liable in expenses.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 3, 1890.

Electricity in the Brooklyn Navy Yard.—One of the interesting sights at the Brooklyn Navy Yard just now is the application of the electric motor for operating metal drills. Four large vessels are now building, and in the immense amount of boring that has to be done it will be hard to get along without mechanical drills. Both steam and electric machines are now in operation; but the latter appear to be far more convenient, and are great favourities with the Navy Yard authorities. The apparatus consists merely of a small motor enclosed in a tight case, which supports the necessary gearing to reduce the speed so as to operate the drill directly through the medium of a flexible shaft six or eight feet long. From ½ horse-power to 1 horse-power is required to operate the drills, which is supplied from the lighting plant in the yard. Two workmen are required to manipulate the apparatus. It takes less than 30 seconds to bore an inch hole through a half-inch plate. One of the electric drills is now at work on cruiser No. 7, the keel of which was laid a short time since; a couple more are working on the armour plates of one of the monitors, and others are in use in various construction work around the yard.

Edison's Electric Traction Experiments.—It is reported that Mr. Edison has again taken up the experiments on electric railroads that occupied much of his time a year ago; but it has not yet transpired whether anything practical is to come of his work. The original plan was to use potentials so low as to enable the track system of conductors to be used without

Digitized by Google

severe leakage. For city work a system of this sort is greatly to be desired, and everyone will watch with great interest the developments that may come from these experiments.

The Consolidation of Electrical Interests.—The rumours of consolidation between the Thomson-Houston and Edison Companies, which have been floating about in an indefinite shape for some months, have at last resulted in the announcement that a powerful syndicate, which is headed by Mr. Henry Villard, and is engaged in some huge railway enterprises, is also taking up electrical matters, and owns, or is about to acquire, large interests in the above companies. Mr. Villard has for some time been identified with the Edison Company; but there is probably nothing like a consolidation on foot, although there may result some understanding between the companies to lessen the effect of business rivalry, which has been very severe. It is not yet known whether any interest in the Westinghouse Company will be acquired by Mr. Villard's syndicate.

The Westinghouse Electric Railway Company.—Of the Westinghouse Electric Railway Company, the organisation of which was announced some time since, little is being heard at present. It has taken some contracts, but has not yet put any apparatus on the market. Its motors, of which there are to be two upon each car, are said to bear a striking resemblance to the Thomson-Houston and Sprague motors in general appearance, although it is understood that a ring armature will be used instead of the Siemens winding, adopted by most of the other companies. Experiments are being conducted in Mr. Westinghouse's private workshop, and very little is allowed to escape concerning the methods or results of what is being done.

CORRESPONDENCE.

LEAKS ON ELECTRIC LIGHT CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The fol'owing remarks on leaks may be of interest to your readers. To thoroughly know the ways, habits, and annoyances of leaks, I recommend students to the incandescent leads of a modern man-of-war. Ashore I imagine in a well-built house the chief danger from damp is caused by the wandering servant-maid and her can of water; at sea we have the more experienced combination of the Clerk of the Weather and Father Neptune, to say nothing of a fire-hose used with great zeal but little discrimination by the sailor during that electrically heart-breaking operation "washing down after coaling." To preserve our circuits in good order it is necessary not only to detect and repair leaks, but to foresee and forestall their occurrence. To do this in modern iron ships, which can scarcely be called "dry" in even moderate weather, and which are a mass of pipes and secondary circuits, it is necessary to know the exact position of every switch, cut-out (of which there are some thousand or so in a large ship), and lead, relative to all steam, water and hydraulic pipes, gun indicator and bell circuits, as well as places where leaks are likely to occur at sea. But, above all, it is necessary to have a keen eye and good nose.

Broadly, leaks may be divided into two classes—earth leaks and contact leaks. Both may be equally dangerous, but the earth leak can as a rule be fairly easily found; the contact leak is extremely difficult to detect.

In answer to your first question in the last issue of *The Electrician* — "Can damp wood, or plaster, damage sound cable?"—I am inclined to say not; but damage may easily be done to wires securely cased in wood, which do not show till the damp gets at them. I will give one example: Ordinary india-rubber and tape-covered wires are often laid in wood-casings, and putty placed round them. The putty grips the insulation in places, and holds it firmly. If a strain be now put on the wire, as in carelessly refitting a lamp-holder or switch, the insulation is very liable to strip, and the fault to remain undetected below the putty; this will not show till water gets at the place. Undoubtedly, a small leak, in damp wood, will increase, though it is not necessary to increase to become extremely dangerous. I take it the following is the life-history of most heated casings through a small contact leak:—

(1) A small leak in the insulation of both wires, most commonly where two branch wires are forked in.

(2) The casing becomes damp and so connects the two.

(3) A slight electrolytic deposition in the pores of the wood; therefore,

(4) Better conduction and a heating of the particles.

(5) Gradual charring of the wood, but still a high resistance.

(6) Circulation of air and the casing on fire.

Only a week ago I had two such cases, one where the leads to a 16 candle-power 80 volt lamp were forked into a submain; there was no sign on the outside, but inside the casing was charred for several inches. The other case, where the paint outside was blistered, was caused by the insulation being damaged by one of the screws of the casing; the casing was charred inside, the leak this time was to earth.

It is this class of leak that is so dangerous. A big leak is nothing, the cut-out goes—that is all; but the small leak works its wicked will with a current totally inadequate to fuse the cut-out.

I do not think the case of a 20-ampere leak likely to occur through a damp casing. The casing would be on fire long before, unless the wires were very close together; anyhow, with 20 amperes running normally in the wires, an addition of another 10 or 15 would certainly determine the cut-out going. A question arises, should cut-outs be put in to fuse according to the number of lamps or the current capacity of the wire? From practical experience I am inclined towards the latter, for an increase in current of a few amperes in a sub-main can be caused by many things, which themselves are practically harmless, such as an accidental rise of a few volts or many small leaks at damp switches and cut-outs. The result of too fine an adjustment means endless trouble and complaints, while the real danger lies in currents for which it is impossible to adjust owing to their smallness.

There is no method that I am aware of with ordinary insulated wires which can prevent a casing catching fire through a small leak through damp wood. I therefore prefer to use my cut-outs solely to guard against my wires heating, and trust to a good look out for leaks, wet places, and blistered paint to prevent fires.

With the lead-coated wires now introduced into the service casings are done away with, and the wires are as wires should be—in sight, with careful fitting and well-soldered joints in the lead piping. I have never heard of complaints; but a badly soldered joint is worse than useless in a damp place. To my mind lead-coated wires laid on a metal strip is the safest possible way to wire. Any fault, dangerous enough to heat the wires, soon causes the cut-out to go, the metal strip protects the wood. The result of my experience of leaks has been: to pray, if leaks occur—and they are sure to—that they may be big ones.—Yours, &c., R. H. BACON, Lieut. R.N.

H.M.S. "Camperdown," July 12, 1890.

PRIMARY BATTERIES FOR LIGHTING PURPOSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, "Electromaniac," seems to have altogether lost sight of the fact that the voltage depends upon the number of cells in series, and that each cell consumes an equal quantity of zinc. His figures, therefore, require to be multiplied by the number of cells used. The amount of zinc dissolved is not per ampere, but per volt-ampere or watt. As no one else appears to have made this correction, I do so, lest any of your less advanced readers may be misled by the statements made.—Yours, &c., F. G.

Underground Telegraph Lines in Germany.—The Direction of the Posts and Telegraphs has applied for the sum of 1,250,000 marks (£625,000) for the extension of the underground telegraph lines on the Bavaria-Saxony frontier from Hof-uber-Chemnitz to Dresden.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Directors of the Stockholm Gas Works require tenders for the erection of a central station for the town of Stockholm, either in whole or in part, which will be received up to September 1st. The installation for which the tenders are invited comprises machinery, accumulators, &c., for 10,000, and underground leads for 15,000 lamps of 16 candle-power. Further details are given in our advertising columns, and specification and full particulars are to be obtained from the Stockholm Gas Works, price 10s. per copy.

TENDER ACCEPTED.—The tender of Mr. C. F. Kearley, of Uxbridge and Kensington, has been accepted for erecting new offices and stores at West Drayton, for the Electrical Engineering Corporation (Limited).

CHEAP GLASS SHADES FOR ELECTRIC LIGHTING.—We have received from Messrs. T. and W. Ide, the well-known glass makers, some excellent samples of cheap glass shades. These are made in five colours by a process of manufacture covered by a patent. The colours are bright, and are specially selected for harmonising with the electric light. Prices range from 6s. to 9s. per dozen. Large quantities are kept in stock, and, we understand, can be supplied at a few hours' notice. A large assortment of glass globes and shades, &c., can be seen at Messrs. T. and W. Ide's Show Room, Glasshouse Fields, Ratcliff, E.

MESSRS. J. AND J. BLAIR, OF KILMARNOCK.—Messrs. Blair intimate that they have added to their business a department of mechanical and electrical engineering, to be under the superintendence of Mr. James Campbell, late of Messrs. Anderson, Campbell and Munro (Limited). Messrs. Blair will manufacture, amongst other things, the Campbell dynamo and arc lamp and also Campbell's patent ship's electric telegraph.

THE "TRICHORD" LIGHT ADJUSTER.—Mr. W. S. Boult, of Liverpool, sends us particulars of a new suspension fitting for incandescent lamps, which he calls the "Trichord" Light Adjuster. A small brass boss with three radial arms screws on to an ordinary lamp-holder, taking the place of and acting as the usual cord-grip. A little brass basin-shaped block is supported in the proper position on the hanging conducting wires by an indiarubber washer inside it, and the block and radial arms are connected by an endless silk cord.

PERSONAL.—We understand that Sir Benjamin Baker has accepted the position of engineer to the Watkin Tower Company.

ELECTRIC LIGHT CARBONS.—Messrs. Cathcart and Peto inform us that they have been appointed sole agents for the sale in this country of Emil Mahla's electric light carbons, of which they are keeping a large stock in London. It is claimed for these carbons that they give an unusually white light. A price list has recently been issued, giving temperatures and cost of both solid and cored carbons.

REMOVAL NOTICE.—Mr. Ernest J. Gillett, late of 26, Red Lion-square, Holborn, informs us that the business of telephone engineer, until recently carried on by him at the above address under the title of the Electric Telephone Company, has been removed to larger premises at Hermitage Works, Richmond, Surrey.

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1890

The 1890 edition of our well-known Directory and Handbook is now ready. The book consists of 850 pages, and contains a mass of most useful information. The DIRECTORY DIVISION consists of more than 400 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is *thoroughly reliable*, even the very numerous changes which take place in the month of January being incorporated. The book is not a mere list of known and unknown Members of Scientific Societies repeated again and again. The Colonial and Foreign Division will be found extensive and reliable. The book has been very favourably reviewed by the Press. The price is 5s. 6d., post free in the United Kingdom.

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The thirty-sixth half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held yesterday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) read the notice convening the meeting and the minutes of the previous meeting, which were confirmed and signed as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said that the resolution which he had to move was :—

"*That the printed report and accounts of the Directors to 31st March*, 1890, *submitted to this meeting be, and the same are, hereby received and adopted. That a dividend on the Preference Shares of the Company to 30th June*, 1890, *at the rate of 6 per cent. per annum, be paid less income-tax; and that in accordance with the Directors' recommendation a dividend be and is now declared of 2s. 6d. per share, with a bonus of 3s. per share, both free of income-tax on the ordinary shares of the Company, making with previous payments by way of dividend on account a total payment of 6½ per cent. on those shares for the year ended 31st March*, 1890."

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the resolution.

The CHAIRMAN said that, before asking them to approve of this resolution, he would, as usual on these occasions, make some remarks upon the report, and give them some general information as to their working during the last six months. The revenue for the half-year ending March, 1890, amounted to £424,023, being a decrease of £11,909 as compared with the corresponding half of 1889. But the balance brought forward from the September half-year account was £61,151, being an increase of £24,535, as compared with the corresponding period of the previous year. They had, therefore, an increased available amount to deal with of £12,626. It would be observed that their dividend on Direct Spanish shares was £246 more than in the corresponding period, and he had much satisfaction in calling attention to the dividend which they had received from the African Direct Company, namely, £1,500, being at the rate of 4 per cent. per annum for the past half-year. The African Direct Company was formed to carry out an important work—the establishment of telegraphic communication with the British Colonies on the West Coast of Africa ; but the local traffic of the line was very small, and even with the subsidy received from the British Government, the Company was unable to meet its working charges. Now, however, that it had a share in the South African through traffic, the African Direct Company was showing a small profit, and they might hope that in the future their investment in that Company would be a fairly remunerative one. The total working expenses for the half-year to March, 1890, amounted to £98,477, being an increase of £6,029. There was an increase of general expenses in London of £738 in salaries, office expenses, rent, stationery, printing, &c., consequent upon the continued development and expansion of the Company, necessitating additional staff and accommodation. Working expenses at stations showed an increase of £4,132, the principal item of which was in the salaries of their station staff at home and abroad which was fully explained and approved at the last general meeting. The number of staff at stations in March, 1890, was 637, against 582 in 1889, or an increase of 45. On the other hand, several of the items under Abstract B showed a decrease, namely, repairs and renewals of furniture at stations £1,109 ; repairs to stations, £423. Depreciation of cable stock was also less by £654. Repairs to cables amounted to £47,520, being a decrease of £1,145. Full details of the expenses of the ships, &c., and cables used on repairs, would be found on reference to Abstract C in the accounts. They would find as a charge against revenue fund a sum of £5,397 for loss owing to a bank robbery at Athens. This loss was incurred in May, 1889. They had not dealt with it until now, as they had been employing every available means to recover at least a portion of the amount. They regretted that their efforts so far had been unsuccessful.

Digitized by Google

After providing for all expenses and interest charges against revenue they were able to recommend a final dividend at the rate of 5 per cent. per annum, and a bonus for the year of 1½ per cent., making a total distribution of 6 per cent. on the ordinary shares. They carried £125,0˙0 to the general reserve fund, which now amounted to £607,000. When he last addressed them he referred to the West Coast system as being fully completed, and which he believed at the time would give them important results. He was glad to confirm that opinion now. Altogether, they were in a position to meet all the requirements in the development of that dark territory which had been so much before their notice for the last few years. As he had remarked on a previous occasion, they were prepared to do their part in connecting that new world with the old, which would be not only to the interest of civilisation, but of material advantage to the shareholders. He had also told them that they had had some little trouble in Egypt. He might mention that, some time ago, he proceeded to that country, and the result of his visit had been that they had settled affairs there in such a satisfactory way, that there would be a substantial benefit to the Company as well as to Egypt itself from their negotiations. Their relations with that country were now in a satisfactory condition and most likely to be so for many years. He had also referred to the forthcoming Conference, and told them that at Berlin they had made considerable sacrifices. At the recent Conference in Paris, the Company was very ably represented. There was not a point that was not fairly discussed, and he was bound to say that the general body of the Conference representing the different European Governments acted, upon the whole, in a very fair and satisfactory manner to the Company. He had mentioned that they had no vote at those Conferences. They could only exercise their influence by placing before the representatives hard facts. As a rule, those facts were fairly dealt with; and he could say, without fear of contradiction, that the relations of the Company with the different Governments of Europe were never better than at the present time. The result had been that they came away from the Paris Conference with more satisfactory terms than they had done from any previous Conference. Small reductions in the Continental tariffs had been made; but he had no hesitation in saying, watching, as he did carefully, the progress of telegraphy, that before another year passed they would recoup the loss thus made by an increase in the number of messages. Their relations with India had very materially improved. That country was represented by a man of considerable intelligence and telegraphic knowledge, and the result was that the principle of give and take had been acted upon with highly beneficial results to all concerned. The Eastern Extension Company were going to reduce their rates, and what that Company did on the one side the Eastern Company had to support more or less on the other. They were, therefore, parties to an arrangement with the Eastern Extension Company whereby the Australian tariff would be reduced from 9s. 4d. to 4s. a word, the Governments of the Colonies guaranteeing to make good half the loss sustained by the reduction. This reduction must necessarily lead to a very considerable extension of business with Australia. Their Red Sea cables had been in operation nearly twenty years, and hence they would not be doing their duty to the telegraphing public if they did not at once prepare for that increase of traffic by laying another cable in the Red Sea from Suez to Aden, which they expected to have completed before the end of the year. They thought it was only fair to pay, as far as they possibly could, for that cable out of their reserve fund, so as not to add their capital, a policy which he hoped the shareholders would approve. He thought that from the statement he had made they would be satisfied that the Company was in a sound and satisfactory condition.

Mr. CLARKSON adversely criticised the general policy of the Board.

The CHAIRMAN, in reply, said that Mr. Clarkson who had come there to make a malicious attack on the Directors was an old servant of the Company, and he refused to answer him. He then put the motion in the usual way, and it was carried unanimously.

Mr. JAMES GIBB trusted that they would not regard it as an improper intrusion into relations more sacred than business relations if he expressed the deep sympathy of the shareholders with the Chairman, in the affliction which they all knew him to have suffered. He would also express their obligations to Sir John Pender and Sir James Anderson for so ably representing the Company at the late Conference. He moved—

"*That the shareholders of the Eastern Telegraph Company (Limited) here present desire to express their sincere sympathy with Sir John Pender and his family in their present severe affliction.*"

Mr. JOHN NEWTON seconded the resolution, and paid a warm tribute to Sir John Pender for the great services he had rendered to telegraphy generally, and to the Companies particularly over which he presided.

Dr. WALLER briefly supported the motion, and bore testimony to the courtesy and kindness of the Chairman in all his dealings.

The vote of condolence having been agreed to,

The CHAIRMAN, on behalf of himself and family, feelingly returned thanks, and the proceedings terminated.

(*A full Report will be given in our next issue*).

Telegraph Construction and Maintenance Company (Limited).

A half-yearly general meeting of this Company was held on Tuesday, at the offices, Old Broad-street, under the presidency of Sir George Elliot, Bart., M.P.

The MANAGING DIRECTOR (Mr. William Shuter) having read the notice,

The CHAIRMAN said: Gentlemen, you are aware that we have no accounts to present at these half-yearly meetings, nor, indeed, have I much to say beyond assuring you that, during the half-year which has ended, we have done as fair a share of work as we could have expected. Our factories are not idle at the present time, and our prospects for the remainder of the present year are encouraging Among the cable work executed I may mention that we have laid a duplicate cable between Australia and New Zealand, about 1,200 miles in length. As regards our general gutta-percha business, independent of submarine cable work, it has been satisfactory.

The proceedings then terminated.

The National Telephone Company (Limited).

The tenth ordinary general meeting of the Company was held on the 11th inst. at the City Terminus Hotel, Cannon-street; under the presidency of Mr. Frederick Richards Leyland.

The SECRETARY (Mr. Thomas Blaikie) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—I propose to address you shortly with a view of elaborating and explaining some of the paragraphs in the report. The first thing that I have to remark upon is the fact that the whole of the amalgamation expenses, by which I mean the Government tax on the increased capital necessary, and the tax also on the transfer from the United and the Lancashire and Cheshire Companies to the National, we have thought desirable to put into the year's working. The great object of that is this: in making up these accounts we have gone upon this principle, that everything that could properly be put to the expenses of the year ought to be put to the year and paid out of the year's revenue. In drawing the distinction between capital and revenue expenditure, of course, there are many things about which there could be no doubt whatever; but in all cases in which there was any doubt as to whether an item ought to be put to capital or to revenue expenditure, we thought it desirable to err on the side of putting it to revenue, leaving capital as little augmented as we possibly could. Of course, in a business like this, the extension of our operations must be provided for by capital; but in all cases we have erred on the side of putting it to revenue, and I think that is a policy which will commend itself to the shareholders generally. Then we come to what, after all, is perhaps the most important thing we have to consider to-day, and that is the concluding lines of the first paragraph:—"In view of the near expiration of the Company's patents, the Directors think it prudent to strengthen the reserve account; and they propose, under Article 113 of the Articles of Association, to transfer to this account £40,000, leaving £11,113. 9s. 7d. to be carried forward to next year." Well, we recommend that pretty much on the same principle that we have adopted in making up the accounts. We think it is a desirable thing to strengthen our position by having large reserves and declaring a moderate dividend, which I think, and I hope you will all agree with me, is not an unsatisfactory one. As it is stated here that is, of course, mainly in view of what is going to happen when our patents are out. We cannot shut our eyes to this fact that competition may arise. We know that one Company is already formed to begin a competing service in Manchester. I dare say you all know that as well as I do. Fortunately, I think I am justified in saying that that Company does not appear to be a very strong one. I think also that they will find that they have a great deal to learn. The first patent expiring is the Bell receiver, which takes place in December of this year. I may tell you, and I believe it is a fact, that it will be utterly impossible for the Company I have referred to to carry out their business, as they say they will, on the expiration of that patent. They might be able to use this receiver for a small exchange with considerable advantage, but in a large exchange they will find it utterly impossible to do so. They will have to wait until the second patent expires in July, 1891—that is the Patent Edison Transmitter. Even when they get that they will find that there are other patents which do not expire until 1893, and which, although I will not say that they are absolutely necessary, are of material advantage in carrying on a good service As for the first patent that expires, I do not think they can carry on any service at all with it—that is the exchange service, which is not very good. I dare say that all of you have read with a good deal of interest the letters that have appeared from time to time in the newspapers both from the Mutual Company and from others who are not connected with that Company, but who seem to take very great interest in telephonic matters; and more especially the speech made by the Duke of Marlborough in the House of Lords. But let us see what their statements are. They seem to be founded principally on one thing: that telephone service abroad can be done for very little. I think that Mr. Provand, in his letter, says it can be done for something like £4. 8s. 10d. But when you come to go into that, what do you find? They compare us with Norway and Sweden, where the low rates are. But what possible comparison, except a very misleading one, can there be between places like Norway and Sweden, or towns like Christiania and Stockholm, and cities like London, Manchester, Liverpool, and Glasgow? But when you go into the matter a little further, what do you find beyond that? In the construction of the lines in Norway and Sweden (and a very large amount of the construction account is for the poles for carrying the wires), the poles are on the spot; whereas we have to bear the cost of bringing them over here and distributing them to the various places where they are required. Take what is more important still, namely, the cost of labour in those countries relatively to what it is here, and there is no comparison. Again, telephone companies there are not subjected to a tax of 10 per cent. on their gross income, as we are. We have to pay that. Moreover, they have to pay nothing for wayleaves in those countries, whilst ours amount to £25,000. These facts are all disregarded. The information given to the public is all on one side of the account, and people are left to find out for themselves these other facts. The Duke of Marlborough in his speech says, "There seemed to be three or four times as many subscribers to telephones as there were in London." Now, let us get at the facts. There are 5,300 subscribers in London, and 7,800 in Paris. Yet the public are told that there are three or four times as many there as there are here. I feel con-

Digitized by Google

fident that we shall get more subscribers. But that is a sample of the reckless statements that are made; and they are most misleading. He says, "The charge for a telephone in London is £20 a year, whereas the average charge for one in all the European capitals is £6 a year." Well, we will take an important European capital to begin with—Paris. I find that the charge in Paris used to be £24 a year. The Government there, as you are aware, took possession of the telephone system, and, of course, as they do not want to make a profit out of it, they reduced the cost considerably. What did they reduce it to? To £16; and there is a wide margin between an average of £6 and £16. In the provinces of France the Company charged 400 francs, which is £16; but the State reduced that to 300 francs, or £12, for underground exchange wires, and £8 for overhead exchange wires. But they make the subscribers buy their own apparatus and pay for the overhead wires. All this is left out of the calculation. In Berlin and throughout Germany they make an average charge of £7 10s. But there again there is no 10 per cent. to be paid to the Government. There is no cost for wayleaves. The Government take the standards on to the tops of people's houses, whether they like it or not; and, if they object, they will take those standards down and lay them at the front of their doors. You cannot do things like that here. Portugal is not of much importance, but in Madrid the cost is £12, whilst in St. Petersburg it is £23. 2s. 6d. In Norway and Sweden it is £4. 8s. 10d. There is another little thing that they do not mention with regard to these countries—namely, that they allow a certain number of conversations in the year, and if subscribers exceed that number they have to pay for every extra conversation. You may get cheapness there, but they give you very little for your money. Some kind friend sent me a Liverpool paper yesterday, stating that we ought to take an example from the United States of America, where they worked the lines so cheaply that they could be brought into a poor man's house. Now, in New York, the rate is from £30 to £36, whilst in Boston it is from £19. 5s. to £24. In Chicago it is £25, in Pittsburg £16 to £20, in Washington £12 to £16, according to distance; in New Orleans £19. 15s., and in Philadelphia £24. On the whole, though we are recommended to go to America for an example, it strikes me we have not much to learn there on the score of cheapness. Their rates are higher than ours by a long way. Those gentlemen when they commence competition will find out in good time all these things for themselves; and I think it is better to leave them to do it. Then the question arises, how are we to deal with this competition? I do not intend to go into any details as to this matter. It strikes me that it would be very like one general showing his plan of campaign to another. But there are some things that are obvious. I fancy that we are all agreed upon this, that in this fight we do not intend to relinquish our position. We intend to take the necessary measures to consolidate and strengthen our position, and to keep the field, whatever those measures may be. I am quite sure that that is the true way of dealing with it. There are two other things which are of the utmost importance. One is the economy of working—the reduction of working expenses; and the other, which I ought probably to put first, is the efficiency of the service. As regards the latter you must not suppose that we have been idle. From the day that we took this business in hand the efficiency of the service has engaged our attention. Taking London as the greatest example, what did we find there? A great many of the switchboards were of an antiquated pattern, and were not effective; and the first thing we had to do was to replace them by others of more modern construction. We have done so, there being only two left, which is a pretty big stride to take in six or seven months. The next thing we had to deal with concurrently was the junction wires—the joining of one exchange on to another. One of the great defects of the London system has been the multiplicity of the exchanges. We have made a considerable reduction of them, especially in the City; and we intend as we go on, if possible, to get the whole of the work done in one or two exchanges. These junction wires have been greatly improved and looped, but there are a large number yet to be done. We have done 350 miles with the best possible material and of the most modern character. We have still 1,200 to do, and we are proceeding with the work. Then we found in all the instruments a large number of battery bells which were old fashioned and exploded, and we have had to replace them by modern ones—magnetos. We have done so in the case of 1,700, and we have 350 still to do. Then the shackles on the poles were antiquated. Nobody would dream of using them now, and we had to replace them by cross-arms and insulators, which give an infinitely better service. We have replaced a third. We should have been glad to do more, but it would have involved a serious stoppage to the service, and we have had to do it as well as we could from time to time. As it is, we have had no end of complaints. These changes involve a certain amount of defective communication; and it has been a subject of great gratification to me to find that the vast majority of those complaints were simply owing to defective service arising from the exchanges which were badly appointed. Then the report says:—"The extension of the Company's business during the past year has been very satisfactory, the gross annual rental from exchange, trunk, and private lines having increased from £343,544. 1s. 1d. on the 30th April, 1889 (prior to the amalgamation), to £392,541. 19s. 1d. on the 30th April, 1890, an increase in the year of £48,997. 18s." Then it goes on to say:—"The important trunk lines connecting London with the principal towns in the Lancashire, Yorkshire, and Midland districts were completed as far as Edgware in January last, and the service proved to be perfectly clear and distinct. Some difficulty was then experienced in running the wires through to London, which was not overcome in time to have the connection completed before the issue of this report. The Directors have every confidence that the communication between London and the north will be established by the end of this month. A large number of additional trunk lines connecting various towns in the provinces have also been commenced during the year, many of which have been completed." You have heard that so often that you may be a little incredulous. As stated in the report, we have every confidence that they will be established by the end of the month; but I am very glad to tell you that late last night we absolutely got the telephone office in communication with Manchester, Liverpool, and Birmingham. It is a very small room, but if some of you would like to visit it I shall be glad to see you. Of course, you understand that having been brought in at midnight, it will be scarcely in working condition for the public for a little time. "These trunk lines supply a much-felt public want, and will add greatly to the strength of the Company." That will be one of our props of support in the face of competition. We can now go pretty nearly all over the country. I cannot say what profit there will be from them, because they are just opened; but all the other trunk lines that we have opened throughout the country have been profitable, returning a fair interest on the money expended on them:—"The Directors believe it most important to continue the policy of developing and improving the Company's system, and of giving greater facilities to the public. The capital required for this purpose the Directors propose to raise by the issue of Debenture stock or Preference shares, as may be found best for the interests of the Company." That depends very much on the state of the market at the time; but we ask you to leave the Directors to do the best they can. Then we say in the fifth paragraph:—"The accrued rental for the year ended April 30, 1890, was £364,704. 17s. 5d., an increase of £45,162 over the accrued rentals of the National, United, and Lancashire and Cheshire Companies for the year before the amalgamation. The working expenses for the year ended April 30, 1890, amount to £148,457. 8s. 9d., being 40·7 per cent. on the accrued rental, whilst the working expenses of the three Companies before the amalgamation were 47·7 per cent. This saving of 7 per cent. is owing to reductions of working expenditure rendered possible by the amalgamation." That pretty well speaks for itself. You have had a larger business carried on at practically the cost of carrying on a much smaller one. We only got into office in July last year, and then we had to consider and make out our plans how to effect these savings. We could not go rashly to work, and reduce this and that, without thinking what would be the effect over the whole system. This saving has really been effected in seven months, and next year I have no doubt we shall be able to give you certainly as good a report as this one. We have also had some difficulty with regard to labour as well as the Post-Office. It is the same with almost every trade in the country. The next paragraph says:—"The Directors have taken over the business of the Northern District Telephone Company (Limited), which is now merged in this Company." That was carried out a month ago. What we did then I think was a wise thing. I am quite sure it was a necessary thing for the Northern District Company, and I think we shall find out that it will be an advantageous thing for this Company. There is no doubt that it is an advantage more especially to the large subsidiary companies to be amalgamated with a strong Company like this. We have carried that out with the two large companies—the Lancashire and Cheshire District and the United, merging them into the National. The first thing gained by that is a saving of working expenses. But you acquire a great deal more than that. You have got a promptness and decision on the part of the Board which could not be attained with three Boards to consult. The policy of this Company is to take in the South of England and the Western Counties on the most favourable terms. Then we say, "The Postmaster-General not having given notice to purchase the Company's business under the power reserved by the terms of his licence, is not now entitled to do so for another period of seven years." You are all, I dare say, aware of that. The auditors, Messrs. Welton, Jones and Co., retire and are eligible for re-election. In a Company like this we thought it necessary to send out the proxies. The shareholders are spread over the whole of the Kingdom. In the old National Company a large number of the shareholders were in Scotland and all through the provinces; and it was necessary, we thought, to give them an opportunity of expressing approval or censure of this report. I may as well tell you that we have proxies amounting to 181,788 shares, out of a total of 468,984, which is a substantial indication on the part of those who cannot attend here that they are pretty well satisfied with what the Directors are doing. On the 4th of July I received a letter from an important shareholder, asking a very pertinent question as to what is to be done with the reserve fund; and I rather gather that his view is that the best thing would be to invest it in marketable securities. I have no doubt the gentleman is present, and if I am misrepresenting what he says he will correct me. He is not only a large shareholder in the Company, but he is a man who has had considerable experience in financial matters; and his opinion is justly entitled to very great weight. When he says "marketable securities," I do not think that is the only point to consider. We ought to invest this not only in marketable securities, but in securities in which there is not much fluctuation in price, because it would be rather a serious thing, when we wanted any money, to find that there was a drop of 5 or 2½ per cent. in the value of the investment. You want easily marketable and perfectly safe security, where there is not much fluctuation; and Consols are the best that I know for that. But I cannot see where the policy is of investing money which will not give you more than 3 per cent. and borrowing more money by way of increasing the capital on which you pay 4 per cent. As a matter of fact, this reserve for the time being has been largely employed in buying up the Northern District Company. At the time we carried out that arrangement we found that we could get better terms by giving the old shareholders the option of paying them in our ordinary shares or in sovereigns. They took the latter, and by that means, I think, we got a much better bargain. I have now to move:—

"That the report and accounts be taken as read, be received and adopted, and that a dividend at the rate of 6 per cent. per annum, less income-tax, on the first and second Preference shares, and on the fully-paid ordinary shares of the Company (excluding the 52,100 new ordinary), be paid for the half-year ending April 30th last, making, with the interim dividend already paid, a total dividend of 6 per cent. for the year."

Digitized by Google

Dr. AUGUSTUS BROWN thanked the Chairman for his lucid statement of the Company's position, and said he approved of giving an efficient service, though they might receive only a moderate dividend.

Dr. GALE asked why it was that they paid only £10 a year at Plymouth for the telephonic service, and whether the £900.000 odd included the antiquated plant of the United Telephone Company (Limited). He did not think they should treat so lightly, as the Chairman seemed to do, the receiver in carrying on a telephonic exchange. He knew from experience that it was of great practical value.

Mr. J. GARNETT observed that the charge for a service in New York was £30, and it was worse than that of London, and ten times worse than that of Lancashire. The consequence was that the charge was being altered to £49, and the people who were now paying £30 were only too glad to pay the higher figure on account of the better service. People had to pay $2 for a conversation of five minutes between New York and Boston. As to the difference of the cost of the telephone in London and Plymouth he thought there was no ground of comparison. He could buy land in Scotland at a penny per yard, but where could they do so in a city like London? The cost of wayleaves, labour, and everything else was different in the two places.

A SHAREHOLDER suggested whether it would not be advisable to have the rest of the second Preference share capital called up at an early date.

Mr. BIDON said that the reserve fund should be exclusively applied to meet contingencies. Supposing, as happened in the case of the United Telephone Company, their wires were swept away by a heavy snowstorm, what would be their position with regard to replacing the wires? He thought it was far wiser to put the reserve fund into Consols or some other security, than to employ it in the business of the Company. He wished to know whether it would not be better to lower the rates with the view of preventing competition.

Mr. LEAKE thought that in the item of £87,174 expenses, the different items should have been separately set out, showing the Directors' emoluments and so forth.

The CHAIRMAN, in reply, thought that if Dr. Gale would apply to the Company he would be able to ascertain why they charged only £10 at Plymouth for the telephone service. As to the Bell receiver, he was not a technical man, but he had taken the best advice he could get, and he was assured that it could not be made efficient. The £900,000 odd was the amount which the investing public considered to be the value, at the time of the amalgamation, of the assets of the United Telephone Company (Limited). The National Company took over all its property and liabilities. It was perfectly clear that it was not to the Company's interest to call up money on which they had to pay a preferential dividend of 6 per cent., when they could get this capital at 4 per cent. At the same time, there was not one of his colleagues, or of the shareholders, who would wish to disregard any honourable understanding that was come to with respect to raising the rest of the Preference shares. There was a difference of opinion amongst them as to the best way of investing the reserve fund, that was whether it should be invested in outside securities or employed in the Company's business. His idea was that it was better to adopt the latter course. He would refrain, for obvious reasons, from answering the question whether they would reduce the rates. Now that the Post Office had made up its mind not to fight the Company, they might be able to get some existing grievances put right. He did not think it would be advisable to let their competitors know the various items of their expenditure; but if Mr. Leake would call at the office, his curiosity could be satisfied.

Mr. J. S. FORBES, in seconding the resolution, said he was sure, though he had not had an opportunity of ascertaining their views upon it, that his colleagues equally desired with himself that they should not let the occasion of their first meeting of the amalgamated Company pass without adverting to the great services rendered to it by the President, who had made personal sacrifices, not only of time, but of health, in the service of their great corporation. Such an amalgamation as they had effected involved questions of policy, judgment, and justice; and they had had great advantage in these respects from the President. They had also benefited greatly by the presence on the Board of Colonel Jackson, the late President of the National Company, and all the other gentlemen forming the amalgamated Board, who have been content to sacrifice personal feeling to the good of the undertaking. He congratulated the proprietors upon the happy inspiration which brought about the fusion of the Companies on terms equitable to all, and the indirect benefits of which had not yet been realised.

The resolution was then put to the meeting, and carried unanimously.

On the motion of Mr. JAMES GODDARD, seconded by Mr. BEGG, the auditors, Messrs. Welton, Jones, and Co., were re-appointed.

A vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

Elmore's Wire Manufacturing Company (Limited).

The first general meeting of the above Company was held on Monday, July 14th, 1890, at the City Terminus Hotel, Cannon-street; Mr. George Smith presiding.

The SECRETARY (Mr. J. Shurmer) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, in the absence of your chairman, Sir John Morris, who is at present out of town, he has asked me to preside at this first meeting of the Elmore's Wire Manufacturing Company. The meeting to-day, as you know, is a formal statutory meeting, without report and without accounts. You will, however, wish to know what the Directors have been doing during the four months of the Company's existence, and we are happy to tell you what is the present position of the Company's affairs. First, as to the subscribed capital. Notwithstanding the adverse condition of the financial world at the time of the launching of this Company, about 500 applicants subscribed for the shares, and an ample allotment was made to carry on the business of the Company. As to our relations with the Stock Exchange, application has been made to it for a quotation and a settlement; and upon the shareholders agreeing to the proposed alteration in the articles required by the Stock Exchange Committee, we shall doubtless have our request granted. A special meeting at the close of this one will be held to pass a resolution for that purpose. Then as to the land the Company has acquired. Twelve acres of freehold land have been secured adjacent to the parent Company's works at Haigh Park, Leeds, and manufacturing buildings are being erected thereon under the responsible supervision and control of our managers. Orders have been given for plant, and these will be followed up judiciously till we complete the factories and set them to work, which we anticipate we shall do before the close of this year. The Company's arrangements for its works have been influenced by the consideration of the many advantages of having them contiguous to those of the parent Company. We can then share with that Company the services of Messrs. Elmore, and so minimise an important item of our working expenses, whilst we shall secure the presence of these gentlemen always at hand. The policy which the Directors have elected to follow has been to work with, rather than against, the wire manufacturing trade; and we are happy to say that a very substantial group of Birmingham wire drawers have offered to take the whole of our output of spirals for 1891, with prospective arrangements for continuing the agreement, and that at a price which will yield us satisfactory results. The advantages of such an arrangement are many and obvious. First we can at once secure an established trade for all that we can make without having to create one for ourselves; secondly, we enlist the interested co-operation of some of the most important manufacturers in the country, instead of having them for our rivals; thirdly, we avoid bad debts, the firms in question being of the highest standing; and fourthly, we are released from capital expenditure for wire drawing, which will enable us to lay down more depositing plant, and so simplify and increase our business. It only remains for me to notice an agreement which we are entering into for carrying out the above offer. The terms have been approved, and the agreements themselves will shortly be executed and exchanged by the parties concerned. The Directors, therefore, feel that they may congratulate the shareholders of the Elmore Wire Manufacturing Company upon the prospects which are before them. Those shareholders who may wish to see examples of our manufactures by this depositing process may see them exhibited at 56, Queen Victoria-street, and they will do well to inspect them.

The SECRETARY then read the notice convening the extraordinary general meeting, held for the purpose of passing the following resolution:—

"The Company may make contracts with any of the Directors upon such terms as the Directors shall think fit, and a Director shall not by reason of the fiduciary relation subsisting between him and the Company be accountable for any profits made by him in respect of any such contract; nor, subject to the following proviso, in respect of any other contract made with the Company in the profits of which he participates, or in which he is otherwise interested, provided that the fact of his being so interested therein, and the nature of his interest, be fully and fairly disclosed by him at the meeting of the Directors at which the contract is determined on, if his interest then exists, or in any other case at the first meeting of Directors after the acquisition of his interest; but in the case of contracts with companies or firms of which any Director of this Company is a member, it shall not be necessary to disclose more than the fact of such membership, provided always that in no case shall such Director so interested vote, or, if he does vote, his vote shall not be counted."

The SOLICITOR (Mr. Hollams) said that the only change made in the existing regulations by this resolution was the last few words, "provided always that in no case shall such Director so interested vote, or, if he does vote, his vote shall not be counted." This restriction was required by the Stock Exchange. He confessed that he did not know how the clause had been omitted in the Articles as originally prepared.

The CHAIRMAN formally moved, and Mr. CARSON seconded, the resolution, which was agreed to *nem. con.*; and the proceedings terminated.

The Direct United States Cable Company (Limited).

The following is the Report of the Directors for the six months ended June 30, 1890, to be presented at the twenty-sixth ordinary general meeting of the Company, to be held at Winchester House, E.C., on Friday, the 25th inst., at 2 p.m.:—

The half-year's revenue (subject to revision on decision of the case mentioned below) after deducting out-payments, amounted to £40,017 1s. 0d., against £39,626. 8s. 5d. (after similar deductions), for the corresponding period of 1889, being a difference of £390. 12s. 7d. in favour of the half-year under review.

The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cables, amounted to £17,616. 5s. 8d., leaving a balance of £22,400. 15s. 4d. as the net profit of the half-year, making with £8,317. 19s. 4d. brought forward from the previous half-year a total of £30,718. 14s. 8d. For the corresponding half-year of 1889 the working expenses and other payments amounted to £16,676. 3s. 9d.

Three quarterly interim dividends of 3s. 6d. each per share, amounting to £31,872 15s., have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with the three interim dividends, 3½ per cent. for the year, being a total distribution of £42,497. An amount of £8,502. 4s. 5d. has been transferred to the reserve fund account, which now stands at £250,000, and the balance of £968. 0s. 3d. on the revenue account is proposed to be carried forward.

Digitized by Google

During the earlier portion of the past half-year the traffic showed a slight diminution as compared with the corresponding period of the previous year, but lately an increase has taken place which it is hoped may be progressive.

The Anglo-American Company having in January last opened offices of its own in New York, the expense of the office at 40, Broadway, in that city, previously maintained as a joint office, is now entirely borne by this Company, accounting for the increase in the expenses during the past half-year. The maintenance of an independent office in New York is regarded as necessary. A station has been opened by this Company at 40, Hope-street, Glasgow. These additional facilities are already producing beneficial results.

A break occurred in the short section of cable on January 19th last, about 122 knots from Halifax, which was repaired on March 30th. On April 10th a fault was removed from the shore end of the same cable near Rye Beach. On May 26th a break occurred in the main cable, which was promptly repaired on the 29th. The breaks in the cables were found to have been caused by vessels' anchors. The repairing operations have cost £4,919. 13s. 5d., which has been debited to the reserve fund account, as heretofore.

The interests of the Company were represented at the International Telegraphic Conference recently held in Paris. In the case of the Anglo-American Telegraph Company *v.* Cie. Française du Télégraphe de Paris à New York, the Appeal to the Council of State, mentioned in the Report to June 30, 1889, is still pending.

Pursuant to the provisions of the Articles of Association, two of the Directors, viz., Charles Meara, Esq., and E. M. Underdown, Esq., Q.C., retire by rotation, and being eligible offer themselves for re-election. Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

United River Plate Telephone Company (Limited).

The following is the Report of the Directors for the year ending the 31st March last, to be presented to the shareholders at the fourth ordinary general meeting, to be held at Winchester House, E.C., on Tuesday, the 22nd inst., at 12 o'clock :—

After paying all working expenses abroad, debenture interest, London and other charges, there is a profit of £34,198. 6s. 5d., from which has to be deducted the sum of £22,334. 17s. 1d. for loss on exchange, leaving a net profit of £11,863. 9s. 4d., increased by the balance of £1,210. 7s. 2d. brought forward from the previous year, to £13,073. 16s. 6d. Out of this, an interim dividend of 2 per cent., or £5,800, was paid in January last ; and the Directors recommend that out of the remaining balance of £7,273. 16s. 6d. a further dividend of 1 per cent., or 1s. per share, free of income-tax, be now paid, which absorbs £2,900 ; that £2,000 be placed to the depreciation and renewal fund, thereby increasing it to £9,000 ; and that the balance of £2,373. 16s. 6d. be carried forward to the credit of profit and loss account for the current year.

As shown in the balance-sheet accompanying the Report, the capital expenditure during the year amounted to £12,772. 8s. 0d. as against £35,070. 2s. 11d. in the previous twelve months.

The shareholders will see from the profit and loss account, that the business of the Company has largely increased during the past year, the gross receipts having been £108,612. 2s. 7d., as compared with £81,866. 2s. 4d. in the year before. Such a development of business has neccessarily increased the working expenses in the River Plate, and the continued depreciation in the currency there has naturally given rise to a necessity for higher wages. In spite of these difficulties, the result of the Company's working would have been very satisfactory but for the serious increase (more especially during the second half-year) in the loss on exchange, which amounted to £22,334. 17s. 1d., as against £14,689. 6s. 8d. in the previous year, the net profits having been thereby so reduced as to make it impossible for the Directors to recommend so high a dividend as last year. But to meet this loss on exchange to some extent, the Directors raised the rates of subscription on the 1st January last, and they are glad to say that the change has been carried out successfully.

The shareholders will remember that the Directors were authorised at an extraordinary general meeting, held on the 9th January this year, to issue Debenture Stock and to convert the then existing 7 per cent. Debentures ; and the Directors are glad to report that out of £100,000 7 per cent. Debentures £97,000 have been converted into 5 per cent. Debenture Stock, and that £29,000 of the same Stock, offered to the shareholders, was largely over subscribed.

Under the Articles of Association the Right Hon. Lord Thurlow and Mr. Frederick Green retire by rotation at this meeting, but, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also retire, but offer themselves for re-election.

Crompton and Co. (Limited).

The following is the second report of the Directors, to be presented at the annual general meeting of the shareholders, to be held at the Cannon-street Hotel, E.C., on Monday, the 21st inst., at 2:30 p.m. :—

The net profits for the year amount to £10,610. 1s. 7d., and after payment of the interim dividend last December, and providing for Debenture interest and other payments, set out in the accounts, there remains a balance of £6,030. 6s. 0d., from which the Directors propose, after setting aside a sum of £500 as a provision for doubtful debts and contingencies, to declare the usual dividend of 7 per cent. per annum upon the Preference shares, and 5 per cent. per annum upon the ordinary shares, carrying the balance forward.

The business of the Company has greatly increased, necessitating considerable extension of the works and large additions to plant. The contract for the public lighting of Chelmsford has been carried out, and the result has given great satisfaction in the town. It is hoped that private consumers will now apply for the light in sufficient numbers to make the contract a profitable one. The installation has cost more than the original estimate, largely in consequence of unexpected and difficult requirements of the Board of Trade.

Very important contracts have been arranged with several of the electric supply companies in London, the principal feature of which is that this Company receives a fixed profit upon the actual cost of the works ; and large orders are also in hand for other companies and firms, the prospects of the present year being in consequence very good.

It is with the greatest regret that the Directors have to record the loss by death, in October last, of Viscount Torrington, Chairman of the Company. In accordance with the Articles of Association, Sir Charles Grant retires from the Board of Directors by rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

NEW COMPANIES REGISTERED.

BLACKMAN VENTILATING COMPANY (LIMITED).—Registered by Gadsden and Treherne, 28, Bedford-row, London, W.C., with a capital of £75,000 in £1 shares. Objects: To purchase from the Blackman Air Propeller Ventilating Company (Limited), and the liquidators thereof, all the business, letters patent of every description ; to acquire the business, letters patent, and inventions of Isaac D. Smead, of Toledo, Ohio, U.S.A.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
VULCAN PHOSPHOR DURO METAL
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

JOHN BENNET LAWES AND CO. (LIMITED).—Registered by Markby, Stewart and Co., 57, Coleman-street, E.C., with a capital of £80,000 in £100 shares. Object: To acquire the business of a chemical manufacturer now carried on by Sir John Bennet Lawes, at 29, Mincing-lane, and the Atlas Works, Millwall.

GRANGEMOUTH GAS COMPANY (LIMITED).—This Company has been registered by Mr. W. M. Anderson, Grangemouth, with a capital of £10.000 in 10,000 shares of £1, to carry on and continue the business of making and supplying gas for providing light, heat, or motive-power within the burgh of Grangemouth and the immediate neighbourhood; to carry on the business of an electric light company, and the business of electricians, mechanical engineers, &c.

BLAKE AND KNOWLES STEAM PUMP WORKS (LIMITED).—Registered by Ashurst, Morris, Crisp, and Co., 6, Old Jewry, E.C., with a capital of £300,000 in £10 shares. Object: to carry into effect an agreement with the George F. Blake Manufacturing Company, of Massachusetts, and the stockholders thereof, which is detailed in Clause 3 of the Articles of Association; to carry on the business of manufacturers of, and contractors for, the sale, letting on hire, erection, repair, maintenance and renewal of steam pumping and other machinery; to carry on business as mechanical, electrical, metallurgical and chemical engineers, iron and other founders in all branches.

VICTORIA TORPEDO COMPANY (LIMITED).—Objects: To acquire letters patent granted to George Read Murphy, electrician, of 9, Fenchurch-avenue, London, for improvements in means and mechanism for propelling, controlling, steering, and exploding torpedoes, adopting therefor an agreement of July 2, made with the said patentee, the particulars of which are not specified in the Articles of Association. Capital £16,000, in £1 shares. Registered, without special articles, July 2, by C. P. Pritchard, Marshall, and Nunn, solicitors, 27, Gracechurch-street, London.

SHAW ENGINEERING COMPANY (LIMITED).—Registered by Robinson, Preston and Stow, 35, Lincoln's-inn-fields, W.C., with a capital of £16,000 in £1 shares. Object: To carry on the business of mechanical engineers, metal founders, &c., at Canon's Marsh, Bristol, in accordance with an agreement, made June 27th, between Edward Shaw and George John Harcourt of the one part and John Bicknell, on behalf of the company, of the other part.

SHERRIN ELECTRIC POWER GENERATOR COMPANY (LIMITED).—Registered by Johnson, 5, Austin-friars, E.C., with a capital of £100,000, in £1 shares. Objects: To adopt an agreement, made July 2, between J. Sherrin, J. V. Sherrin, T. Richardson, and H. F. Woodgate, of the one part, and G. M Canham, on behalf of this Company, of the other part. There shall not be less than three nor more than seven Directors. The first shall be appointed by the subscribers to the Memorandum of Association, with the proviso that one be nominated by J. Sherrin, J. V. Sherrin, T. Richardson, and H. F. Woodgate. Qualification, 100 shares. Remuneration, £2,000, divisible.

SMITHY BRIDGE IRON AND STEEL WORKS (LIMITED).—Objects: To acquire the business of the Paragon Works (Limited), mechanical engineers, and founders and workers in metal, at Smithy Bridge, near Rochdale, and carry on the same and others analogous thereto. Capital, £32,000, in £10 shares, of which 1,600 are 8 per cent. Cumulative Preference shares.

CITY NOTES, &c.

ALLGEMEINE ELEKTRICITATS GESELLSCHAFT.—The resolution for the increase of the capital of this Company which is to be put before the shareholders at the meeting on the 28th inst., is intended to enable it to carry out some new undertakings, the most important of which is the addition to its business of an electric traction branch. A horse tramway in Halle has already passed into the hands of the Company, and a beginning will be made here and in two other large towns. It is also intended, we understand, to acquire, in conjunction with Messrs. Siemens and Halske, an interest in the Tudor accumulator factory of Messrs. Einbeck and Müller, at Hagen.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 11th amounted to £4,734.

AMALGAMATIONS IN AMERICA.—The *Financial News* is responsible for the following:—"A deal involving upwards of $5,000,000 and including a transfer of a controlling interest in the Badger Electric Light Company, the Edison Light Company, and the Cream City and Milwaukee Street Car Companies, is said in the American papers to have been practically consummated. The purchaser is the so-called Villard syndicate, including Henry Villard, and Ryan, the Pittsburgh capitalist. But Milwaukee capitalists will still retain an interest in each of the corporations, although there is a complete change of owners in the Badger Electric Light plant. The purchasers outside of the Villard syndicate are the same Milwaukee men who are interested in the Edison Electric Light plant now being built."

COMMERCIAL AND INDUSTRIAL FINANCE.—Last week we published some extracts from the *Financial News* giving interesting figures showing the appreciation in value of the shares of various Electrical Companies, together with the sums which had been returned to the shareholders in dividends. Our contemporary yesterday returned to the subject, and gave similar figures with regard to a number of companies which, although not quoted on the London Stock Exchange, are freely dealt in on the provincial markets, and are quoted in their weekly lists; and we again extract information relating to companies connected with the electrical profession:—

—	Par value.	Present price.	Capital subscribed.	Market value.	Returned in dividends.
			£	£	£
Birmingham Small Arms & Metal	5	15	203,150	609,450	247,780

Do. Def. Profit Debs.	100	101	80,000	80,800	38,000

DIRECT UNITED STATES CABLE COMPANY.—The Board of Directors of this Company have resolved to recommend a final dividend of 3s. 6d. per share, free of income-tax, such dividend to be payable on and after the 26th inst., making, with the interim dividends already paid, 3½ per cent. for the year ending 30th June last, carrying forward £968. 0s. 3d., after having transferred to the reserve fund account £8,502. 14s. 5d., making it up to £250,000. The transfer books of the Company will be closed from the 11th to the 25th July, both days inclusive.

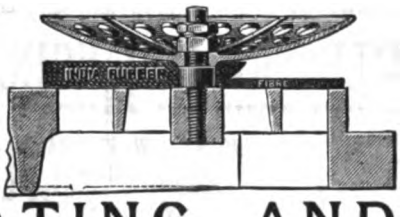
EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY.—The Directors of this Company have decided to recommend to the meeting of the shareholders, to be held on the 28th inst., that a dividend at the rate of 7 per cent. per annum on the A shares for the half-year ending June 30, 1890, (making 7 per cent. for the year), and a further dividend of 4 per cent., in completion of payment of arrears of Cumulative Preference Dividend for the year ending June 30, 1884, and a further dividend of 4 per cent. in respect of arrears of Cumulative Preference Dividend for the year ending June 30, 1885, free of income-tax, be distributed in accordance with the provisions of Clause 87 of the Articles of Association.

GLOBE TELEGRAPH AND TRUST COMPANY.—The Directors of this Company recommend, subject to audit, the payment of a final dividend of 3s. per share on the Preference shares, less income-tax, and of 4s. 3d. on the ordinary shares, income-tax having been already deducted, making, with previous payments, a total dividend for the year of 6 per cent. on the Preference shares, and of 5 per cent. on the ordinary shares, as against 4⅝ per cent. for the preceding year, and carrying forward £108. The meeting of shareholders takes place on the 29th inst. at Winchester House, E.C., at 1 o'clock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 11, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,644.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 636.—Vol. XXV. FRIDAY, JULY 25, 1890. Price Fourpence.

NOTES.

The occasions on which it is necessary that political questions need appear in these columns are happily rare, and we did not intend that the second leading article of last week should be one of these; but we can neither refuse to allow Mr. Fawcus to offer his criticisms, nor can we let his letter pass in silence. We are utterly opposed to Socialism. We hold that individual enterprise is the *régime* under which this country has attained her position and under which progress is to be made. The position of the Post Office is no more one of State Socialism than is the War Office. The State purchase of the telegraphs has proved to be a great success because telegraphic communication necessitates a centre. We look forward to the purchase of the telephones because a centre, or an organised system of centres, is yet more necessary than in the case of the telegraphs. The subscribers of the South of England Telephone Company are most anxious to be connected with the National Company's system, but co-operation and organisation are prevented by trade rivalry or financial complications. If in the hands of the Post Office the engineering and instrumental work of the telephones is done as well as that of the telegraphs, English telephony will be as unrivalled as is English telegraphy. Postal communication should be carried on, as is universally the case, by the Government; but not as a source of revenue. The telegraphs will, probably, never repay the purchase price, and press telegrams are carried at a large loss, which constitutes a Government subsidy to the newspapers. The Chamberlain Electric Light Act is on another footing. The supply of electricity is a commercial undertaking, and should, therefore, be carried out by private enterprise.

Birmingham is to be congratulated on the thorough style in which the Bristol-road electric tramway has been carried out. The work has been done on a very different scale to that of the numerous experiments which have contributed so little credit to traction by accumulators in this country. Many of these, no doubt, have been restricted to the experimental stage through lack of capital, and the work too often has been carried out with make-shift appliances in a merely experimental manner. In more than one case the designs and general ideas have been good, and capable electricians have been employed to carry them out. In some instances the history of the failures has been recorded; in others, the struggles have been forgotten. The idea of running tramways by a syndicate or a company at so much a mile for the tramway company is one which does not commend itself to a contractor. At the best it affords on the one hand a somewhat remote chance of recouping the cost of an extensive experiment; and, on the other, it enables the Directors of the tramway company to watch, without any pecuniary risk, the result of the trials. Enough has been done in the way of experiment to show to engineers that electric traction by accumulators is, under proper conditions, a practical possibility; but nothing has yet been done to convince the public that the system is remunerative. No respectable balance sheet has been published from actual costs; but we are persuaded that it merely needs a plant of the thorough character of the one at Birmingham, and designed and carried out by a competent staff of experienced and qualified engineers, to prove that the system is sound, and that the failures of the past have been due to the lack of that completeness which is to be found at the Bournbrook terminus of the new line. The Birmingham Electric Tramway has a curve of 40 feet radius on a gradient of 1 in 28, and a gradient for about 200 yards of 1 in 32. Heavy gradients are the most serious obstacle to the storage system of electric traction; and we hope that as the rest of the line is easy no difficulties will arise on this score.

Mr. Verity calls attention, in a letter which was crowded out last week owing to late Edinburgh news, to the multiplicity of rules under which contractors for wiring have to work, and suggests that adherence to the regulations of the Institution of Electrical Engineers should be sufficient. It has been said that these were never intended to supersede specifications; but are not specifications the exception rather than the rule? In the majority of cases of private house-wiring the owner asks a contractor to give an estimate for "putting in the electric light;" the contractor being either properly qualified to carry out the work, or merely the builder who is doing general repairs, or perhaps a sanitary "engineer," *i.e.*, a plumber and bellhanger. It is not fair to say that builders should not be allowed to wire houses. We know of one now in progress, where the work is being carried out by the electrical staff of a well-known builder in a most thorough and neat style; while the wiring of well-known electrical firms is sometimes a pitiable bungle. The contractor, if he is a qualified electrical engineer, will generally send some kind of statement of what he proposes to do, with his estimate; and this is often the only specification that appears. If the house is insured in several different fire offices, the contractor has no choice but to work

Digitized by Google

in accordance with their respective rules, or rather in accordance with what his experience tells him will be the interpretation of these rules by the different inspectors, and in accordance with the regulations of the supply company, or companies, in whose district the house is situated. As far as we are aware, there is no absolute contradiction among them. One set may dictate a higher insulation resistance than the others, in which case the latter may be ignored. Another may call for earthenware tubes for passing through walls. These must then be provided, although no other rules demand them. A quarter of an hour's work would settle the critical demands of as many different sets of regulations as are likely to be imposed in any one case.

WHEN a consulting engineer is employed to give a complete specification of the wiring of a house, we do not see that he should be expected to extract the maximum demands from all the rules, and embody them in his specification. It should be sufficient for him to specify his wishes on all points that do not appear in the rules, and to add that the work is to be carried out in accordance with the rules of the Institution of Electrical Engineers, of the various fire offices, and of the various supply companies concerned. The real trouble lies in the arbitrary interpretation of the rules by the different inspectors or surveyors. That the rules should be flexible has been conceded over and over again; the rapid growth of the industry necessitates it. An inspector is within his rights, we believe, in condemning the old-fashioned wooden lampholders and switches that were common six years ago; but he has no right whatever to assert that the onus of replacing them by modern fittings must be borne by the contractor who supplied them. Careful inspection by surveyors from the insurance offices, though often causing unnecessary annoyance, has been of immense service. They have done their work thoroughly, in the face of considerable opposition, and their duty has often been unpleasant. We feel confident that the insurance offices will suffer if they cause the electrical industry to suffer; and as the effect will be felt most by the office which offends most, while it is evenly spread over the electrical trade, there is every reason to suppose that the matter will soon right itself.

THE loss of energy due to hysteresis and FOUCAULT currents are points in the theory of transformers which are still very obscure. The separation of these heating effects from each other, and the influence which the frequency of the current and the temperature of the core have upon their magnitude, are important matters, to which little attention has yet been given. The analytical method of studying the action of transformers is unsatisfactory, since it depends on the erroneous assumptions that the coefficients of induction are constant quantities, and that the waves of potential follow a simple sine law; and it is thus highly important to obtain the curves showing the actual values of the electromotive force and current at different parts of the alterna tion. Unfortunately, the experimental difficulties in the way are considerable. Not only is the apparatus required very complex, but the uncertainty due to leakage and other sources of error is great enough to cast doubt on most of the curves hitherto published.

THE shape of the potential curves obtained with alternators was one of the many important subjects alluded to at the Institute of Electrical Engineers, in connection with Mr. MORDEY'S paper on "Alternate-Current Working;" and at the end of the discussion a method of determining the curves was described, and it was announced that some striking results had been obtained with the Mordey Alternator. As far as we are aware, these results have, however, never been printed, and as yet the best work which has appeared in connection with this subject, has been carried out at the Cornell University. The first portion of this work, due to Prof. RYAN, was published by us in January of this year. A supplementary Paper by Messrs. HUMPHREY and POWELL appeared in our issue of last week, while in another column we reproduce an additional contribution by Prof. RYAN. The success which has attended these efforts appears to have been due in great measure to the employment of an electrometer of novel construction.

THE work of Messrs. HUMPHREY and POWELL had reference to a transformer of considerable size and high efficiency, the object of the experiments being to determine the influence of FOUCAULT currents on the shape of the curves and on the efficiency of conversion. Prof. RYAN, in his second Paper, is only concerned with the connection between the temperature of the core and the loss of energy from eddy currents; and his transformer, the construction of which was determined by the phenomenon which had to be investigated, was very small and badly designed from a practical point of view, its efficiency never exceeding 30 per cent. The Papers are of interest, since they indicate two distinct methods of separating the heat waste arising from hysteresis and FOUCAULT currents. Hitherto, the best method of separation has been to vary the frequency of the current. Prof. RYAN, however, accomplishes the same object by varying the temperature of the core, and also by comparing the curves obtained from EWING'S hysteresis experiments with those deduced from the current and magnetisation curves.

PROBABLY not one student in twenty who has grasped the idea of OHM'S law has ever doubted its absolute truth; there seems to be such a simple completeness about it. But MAXWELL has asserted that it is a purely empirical assumption, and relies on experimental evidence alone. The work of Prof. CHRYSTAL, in 1876, who determined its truth to a degree of accuracy which is rarely attained in any physical measurements, has appeared to some to be as unnecessary as a minute experimental investigation of the accuracy of the parallelogram of forces. The point lies in the question, is the resistance of a conductor constant for all currents, *apart from considerations of temperature or magnetisation or other indirect effects?* If a wire has a resistance of one ohm when two or three hundredths of an ampere are passed through it, will it still remain one ohm when a pressure of several hundred volts forces a heavy current through it? Will the great density of the current break down

Digitized by Google

any part of the structure of the conductor, or alter its conductive properties? That alone can be settled by experiment. Dr. OLIVER LODGE has sent us an interesting letter on this subject from Prof. CHRYSTAL to Prof. FITZGERALD, which will be found in another column. In connection with this subject we may draw attention to a letter which will be found in our columns from Prof. SILVANUS THOMPSON, who, while clearing one of the issues raised by Professors LODGE and CHRYSTAL, raises another which can scarcely be said to make the subject more simple than before.

AT the close of the strawberry season and the commencement of a little summer weather, a short article in *L'Electricien* on "Revivification Électrique des limes et fraises" seemed to be very appropriate, but on further examination of the paragraph, assisted by our dictionary, we discovered that "limes et fraises," in the present case, mean files and rasps. The method of recutting files, saws, scythes, and other tools by acid, generally a secret mixture, has been the subject of many a query in the *English Mechanic*. It is obvious that where acids are used to dissolve metal, the result may be hastened or controlled by an electric current, as in the etching process, described in another column. In the present case, according to *Le Génie Civil*, where a more complete description is given, the files are suspended in acidulated water, with carbon plates. The tools are connected as anodes. The water is decomposed by the current, and it is suggested that the oxygen goes "energiquement" to the bottom of the teeth which are attacked, the hydrogen forming little bubbles on all the projecting points which thus become protected. Chrome steel is said to give particularly good results under this treatment. The process occupies about 20 minutes. We are somewhat sceptical about the obliging way in which the oxygen goes to work, nor do we see how both oxygen and hydrogen are given off at the same pole, but no doubt the protection of the bubbles of hydrogen constitutes an improvement on the old and doubtful idea of recutting by acid alone.

Paddington.—The Provisional Order granted to the Metropolitan Electric Supply Company for lighting this parish has been confirmed.

The Henry.—The American Institute of Electrical Engineers has passed a resolution, in very formal phraseology, recommending that the unit of self-induction should be called a "henry."

The Electrical Standardising, Testing and Training Institution.—The new session of this Institution, which is under the direction of Mr. H. E. Harrison, B.Sc., begins on Wednesday, September 17th next.

Discovery of Platinum in Mexico.—It is reported that Mr. Flavio Lobato, a well-known mining engineer and analytical chemist, has discovered platinum in some ores from the Las Yedras mines in the State of Sinaloa.

Electrical Treatment of Hæmorrhage.—Dr. Eugen Boér has successfully applied faradisation to cases of profuse internal hæmorrhage, applying the negative electrode to the affected part, the positive pole being pressed against the skin.

The Working Efficiency of Secondary Cells.—We are informed that it has been arranged that the discussion on this valuable Paper will be continued when the meetings of the Institution of Electrical Engineers are resumed in November.

Restoration of Telegraphic Communication with Australia.—Telegraphic communication with Australia, which it will be remembered was interrupted by an earthquake, was restored on the 20th inst.

Paisley.—At the monthly meeting of the Town Council on the 17th inst. it was agreed to oppose the application by the Scottish House-to-House Electricity Company for a Provisional Order to supply electricity in the burgh for public and private purposes.

Tivoli.—The Central Station (which it is hoped will be finished in August) is to contain nine Girard turbines, six of 350 horse-power and three of 50, and nine alternators, six giving 45 amperes at 5,100 volts, and three of 180 volts and 150 amperes.

Nottingham.—On the 18th inst., the Town Clerk of Nottingham received a cheque for £3,000 from the Drapers' Company in aid of the new Technical Schools in that town, to the charge of which Mr. William Robinson, late of the City Guilds Institute, Finsbury, has been appointed.

Hamburg.—It is said that the Senate have consented to a proposition for the electric lighting of the Hauptstrassenzug. The Rathhausmarkt and the old Jungfernstieg are already lighted by arc lamps, which will in time be also installed in the new Jungfernstieg and in Alsterdamm.

The Peral Submarine Boat.—In view of the recent successful trials with Lieutenant Peral's electric submarine vessel, the Minister of Marine has appointed a Commission to report upon the advisability of the Government ordering the construction of several submarine torpedo boats.

Robbery of Platinum.—The four prisoners who were convicted at the last London County Sessions of stealing £800 worth of platinum from the Brush Electrical Engineering Company were sentenced last week to terms ranging from five years' penal servitude to seven months' imprisonment.

Crystal Palace District.—The Bill confirming the Provisional Order for this district, which includes a part of the area controlled by the Lewisham Board of Works, and small portions of Beckenham, Camberwell, Lambeth, and Croydon, was passed last week by a Committee of the House of Commons.

British Museum.—In February, March, and April, an average of 635, 367, and 297 visitors was recorded during the evenings between 8 and 10, when the eastern and the western galleries were alternately open. This, says *The Times*, may be fairly regarded as an adequate justification of the experiment of opening the galleries at night.

Berlin.—The development of the Berliner of the Elektricitäts Werke is shown by the following table, giving the number of ampere-hours supplied for the month of August in each year since the Company was started:—

Year.	1885.	1886.	1887.	1888.	1889.
Ampere-hours	1,462 ...	5,875 ...	7,827 ...	13,290 ...	22,000

Aviles.—An installation of electric light is being arranged at the thriving town of Aviles. A rich inhabitant (the Marquis of Pinaz del Rio) is going to present the town with a complete central electric lighting station. The town is favourably situated for coal, so that altogether the cost per unit to the inhabitants will be remarkably small. The plant has been ordered in the United States.

Munich.—The gas company of this town, which has long been an obstacle to the adoption of the electric light, has reduced the price asked for their works to 5,000,000 marks (£250,000). At this price the Municipality will probably take over the concern. As gas costs 23pf. per cubic metre, that is nearly 6pf. (about ¾d.) per 16 candle-lamp hour, the inhabitants are to be congratulated on this movement.

Telephonic Communication between London and Liverpool.—The two trunk lines are now complete, each having a continuous metallic return. At present Manchester and Bradford are reached through Birmingham; but when the traffic increases, an independent pair of wires will be run to each town. One of the present trunk wires will be devoted to the use of the London and provincial Stock Exchanges.

Digitized by Google

Telegraphic Progress in South Africa.—The Chartered South African Company's line of telegraphs has now been completed as far as Ramoutsa. The first message transmitted over the new line was one from the Chief Ikening to Sir Sydney Shippard, Administrator of British Bechuanaland. The Company is now laying the wire from Ramoutsa to Meschudi Lindewe's Town, which is to be the next station.

Wimbledon.—At a sitting of the Local Board last week the resolution in favour of electric light passed at a recent meeting of the Board was rescinded in favour of another postponing the project till September, 1891. The Local Government inquiry which was shortly to have been held to obtain the consent to borrow the £30,000 required to carry out the work, will not now take place for another year.

The Radiomicrometer.—In an interesting communication by Prof. C. V. Boys to the Royal Society on measurements of the heat of the moon and stars by means of his radiomicrometer, he gives an account of a test with a candle at 250·7 yards distance, which gave a deflection of 38mm. If ¼mm. be taken as the smallest deflection which can be observed with certainty, the instrument, as made and used by him, would show the heat of a candle at 1·71 miles distance, neglecting the absorption by the air.

Electric Treatment of Sewage at Salford.—Experiments are now being conducted at the Salford Sewage Works on an electric system of sewage purification. The water runs along a conduit in which are plates in circuit with a dynamo. The current precipitates the foreign matter from the water, whilst the effluent flows off at the end. The only drawback is that skilled attendance is necessary, and that this adds to the cost. Various Corporations and Local Boards are sending to see the process with a view to its adoption.

Aberdeen.—The Provisional Order sought by the Town Council of Aberdeen provides that the mains shall be laid within two years from the passing of the Bill confirming the Order. The undertakers are entitled by the terms of the Order to charge consumers at the following rates: For any amount up to 20 units, 12s.; for each unit above 20, 9d. per unit. It is also provided that in cases where the undertakers charge for the quantity of current used, similar rates to the above shall be charged, the potential being assumed to be constant.

City and Guilds of London Institute.—Particulars will be found in our advertisement columns of the various courses of instruction to be held during the next session, which commences on September 30th next, at the Central Institution, South Kensington. They are comprehensive in character, and include lectures adapted to the requirements of those who are preparing to become civil, mechanical, or electrical engineers. At Finsbury Technical College the term commences on the 7th of October, both in the day and evening departments.

The Electric Experiments on the Metropolitan.—The Directors of the Metropolitan Railway Company regret that the negotiations which were in progress at the date of their last report for a trial of electric traction on their railway have not resulted in a practical experiment. The use of a section of the railway beyond Neasden was offered, but the electrical engineers stipulated that the experiment should be made on a part of the Inner Circle. To this proposal, having regard to the nature of the traffic on that part of the system, the Directors were unable to agree.

Dresden.—A site for the central station has at last been selected. It will be built on a portion of the town timber-yard in the Lobtauerstrasse. Four thousand marks (£200) have been voted by the Town Council to conduct an investigation as to the best means of utilising the available water-power. A concession has been granted to a civil engineer and a firm of bankers in Dresden authorising them to establish a network of cables, for purposes of transmission of power and electric lighting, direct from some coal mines, through 168 industrial towns in Saxony, to Dresden.

Annual Dinner.—On Saturday last the *employés* of Messrs. Poole and White took their first annual excursion. The party, which numbered just over 30, dined at the Elephant and Castle Hotel, Pangbourne. Mr. J. Tryon, the chairman of the Company, presided, and referred to the success which had attended their efforts during the first six months of their existence, and said it was due in great measure to the excellent *esprit de corps* of the *employés*. Mr. Heaver, who occupied the vice-chair, proposed the toast of "The Board of Directors," to which Mr. Poole suitably replied. After a very enjoyable afternoon the party returned to town.

Lineff Tramway.—A very favourable report has been made on this system by Mr. Kapp, who calls attention to the novelty of the double set of magnetic rails. He has tested the line by taking a steam roller over it, and then drenching it with water for 26 hours, after which no fall of insulation was found, the resistance being 3,400 ohms. Tests at different speeds showed that two feet of rail under the car at either end were out of circuit. The only criticism made in the report relates to the power required to propel the magnet. This amounts to only half a horse-power at seven miles an hour, and Mr. Kapp indicates means of reducing it.

The Iron, Hardware, and Metal Trades Pension Society.—The Duke of Norfolk presided over a meeting of the supporters of this charity on the 18th inst., at his residence, Norfolk House, St. James's-square. It was established in 1843, and its annual income amounts to only £3,400. Some practical suggestions came from Mr. H. S. Kennard, who hoped that an appeal would be made to the Marquis of Bute and other influential representatives of the iron trade. Sir George Chubb proposed that residents in and around Sheffield should also be approached; and it was decided to ask the Marquis of Hartington to preside at the next dinner.

Result of Gas Monopoly at Montlucon.—The Montluçon Gas Company, according to the *Gas World*, went to law with the Municipality for allowing an electric company to come in and use the streets for carrying wires in the face of the gas company's monopoly. The gas company won its case; but its victory has turned out disastrous to it. The electric company was dying; but the public of Montluçon disliked the action of the gas company and came to the support of the electric company, which has been vigorously set on its feet. It appears that the gas company's concession expires in 1895, and will not be renewed after what has taken place. On the contrary, it will have to take up its pipes and restore the streets.

Discharge through a Lightning Arrester.—The following description of a lightning stroke has been sent to the *Victorian Telegraphic Journal* by Mr. James M'Carter, of Melbourne:—"Last Monday night (3rd March), during thunder and lightning, without rain, I 'cut out,' and shortly afterwards was shocked by seeing the office apparently ablaze, and hearing a terrific report, similar to that of a gun, but much louder. I fully expected to find the whole front of the office smashed in, and could hardly credit, on examination, that the only damage done was several of the screw points of arrester fused. The point of one screw was flattened on to the centre plate, resembling a small coin. I scraped this off, and found there was an indent on the earth plate."

Water Power at Sheffield.—The Water Committee of the Town Council, at their meeting held on the 16th, considered the question of a supply of electricity for public and private purposes within the borough of Sheffield, and passed the following resolution upon the subject:—"That in view of the probability of the Corporation obtaining power to supply electricity for public and private purposes in the borough, this committee desires to call attention to the water power connected with their several wheels in the Rivelin, and to suggest that any electrical engineer employed by the Corporation should put himself into communication with Mr. Eaton, for the purpose of ascertaining how far such power might be available for the purpose in question."

Locle.—An interesting example of an hydraulic electric light and power station was recently inaugurated at Locle, in Switzerland, which is situated in a deep valley, the far end of which is terminated by a high ridge, behind which a large reservoir has been established. Water is conducted in pipes from the reservoir to some turbines situated at the foot of the ridge. These turbines are coupled direct to 125 horse-power Thury dynamos. The current, which is at a pressure of 180 volts, is taken to the town itself, three kilometres distant, by a

Digitized by Google

three-wire circuit. At present 185 lights are employed for public, and 1,500 lights for private purposes; 50 horse-power is also absorbed by motors, ranging in size from ½ to 6 horse-power each. The work was carried out by the municipality.

The Western Union Telegraph Company.—An explosion at this Company's offices in New York occurred at 7 o'clock on Friday morning in the battery room on the sixth floor; and the flames, which immediately broke out, soon spread to the portion of the building above, including the operating room and the offices of the Associated Press, both of which were gutted, while the lower floors were drenched with water. The loss is estimated at $250,000. The wires, with the exception of the cable lines of the Western Union Company, were concentrated in the building, and the result of the fire was that the service was greatly crippled. Business on the Exchanges in New York and elsewhere was delayed, owing to the absence of despatches. Only about 40 operators were on duty at the time, and all succeeded in effecting their escape.

Edinburgh.—Intimation was given on behalf of the following four Companies of their intention to apply to the Board of Trade in the next Session of Parliament for Provisional Orders for the supply of electricity within the area of the city:—The Scottish Electric Supply Company, the Scottish House-to-House Electricity Company, the National Electric Supply Company, and Latimer, Clark, Muirhead, and Co. Mr. Auldjo Jamieson said the Council were pledged to take the initiative in this matter themselves; and he moved that it be an instruction to the Lord Provost's Committee to take immediate steps to redeem the promise which they gave last year, and upon which these Provisional Orders were not proceeded with. It will be remembered that the Council promised that they would carry out the Orders themselves, and had no intention of applying for these for purposes of obstruction.

Electricity and Etching.—The *Papier Zeitung* of Berlin announces that an important discovery has just been made in etching, and especially in photogravure. As usual, the drawing is traced on a plate of zinc, either by an artist or by photography, with any suitable etching ground. This plate, backed with asphaltum, is laid in a bath of dilute acid. It is then put in circuit with a dynamo, the other pole being merely placed in the acid. When a current is allowed to pass, the acid attacks the metal with surprising rapidity. A few minutes suffice to bite the plate, and the depth of the etching can be easily controlled. It appears to us that the action is probably due to the depolarization of the surface of the metal, which in the ordinary method of etching becomes covered with a film of hydrogen, or, at all events, with a number of minute bubbles, which make the biting irregular unless the plate is incessantly rocked and brushed.

A Double Local Board Difficulty.—The Lancashire and Cheshire House-to-House Electricity Company are likely to have considerable difficulty with their Provisional Order for the districts of Stretford and Moss Side, near Manchester. According to their present plans they intend to build one central station for the two districts, and had applied and practically obtained an order for that purpose; but the authorities of the two districts desire to keep separate accounts, in the way of which the Board of Trade see "very great difficulty;" and there is also a difficulty caused by the fact that Stretford might be opposed to Moss Side acquiring the works at the end of 20 years. The Moss Side Local Board contend that the Company had no right to couple them with Stretford; and at their meeting on Monday a sub-committee was appointed to confer with the Stretford Board as to the advisability, under the circumstances, of opposing in Parliament the confirmation of the Provisional Order.

Water Power from Niagara.—Under the title of the Cataract Company, a syndicate in the United States proposes to utilise the water power of the Falls on a very extensive scale. There is an effective fall of about 140ft., and it is estimated that 4 per cent. of the present volume of water would yield 120,000 horse-power. The scheme is similar to one proposed a few years ago, and consists of a canal from which the water is to be supplied to turbines in vertical shafts, discharging by a tunnel passing under the town of Niagara. A tract of land above the district, purchased by the Government as a free park, is to be used for mill sites, while a considerable portion of the power is to be transmitted to Buffalo, at a distance of 18 miles. The Company have adopted the singular course of appointing an International Commission of scientific authorities, to advise them on the matter. Among the members of this Commission are Sir W. Thomson, Prof. Mascart, Col. Turrettini, Dr. Sellers, and Prof. Unwin.

Two New Insulating Materials.—The Roessler and Hasslacher Chemical Company of New York are introducing a new insulating material of remarkable qualities invented by the German chemist, Dr. Kunheim. Isolatine is said to be a bituminous viscous liquid mass, suitable for all purposes of insulation protection to electrical conductors. Its merits are that it withstands all aerial and subterraneous influences (moisture, changes of temperature, sewer and coal gases and acids) and its unchangeable toughness. It does not grow brittle or porous, but retains its elastic gum-like consistency under all conditions. Another insulating material, known as "fibrone," which is manufactured by the Fibrone Manufacturing Company, New York, has been recently submitted to the Merchants and Manufacturers' National Laboratory in that City, where it has been analysed and pronounced an excellent substitute for hard rubber. This substance is made in sheets or other forms, which can be sawed, drilled and turned with ease

Glass Insulated Wire.—The *Electrical Engineer* of New York reports that a Mr. Thomas S. Reed has devised a conductor in which the principal insulation is afforded by a layer of spun glass. The method employed consists in first winding the wire with slack-twisted yarn, either cotton or woollen, and overlaying it with longitudinal strands of spun glass. Outside of these a strand of spun glass, intermixed with silk, is wound in a close spiral, and over that a braided covering of cotton, wool, hemp, flax, silk or fine wire. The whole is coated thickly with paraffin or thick varnish, if the wire is to be exposed to dampness. If the wire is to stand hard usage, all the glass strands are loosely twisted with silk, flax, or other suitable fibre, before being applied. The wire can be glass-wound a number of times if necessary, but twice is generally sufficient. The first winding, which acts as a cushion, holds the glass strands in place, and the spiral row compresses them into an impervious surface. For extra security another spiral is wound the reverse way.

Lane Fox Patents.—With reference to our Note in last week's issue, the Managing Director of the Lane Fox Electrical Company writes as follows:—

"I trust you will allow me to correct you upon one or two points. You state that this Company was formed 'with a capital of £100 to collect royalties.' This does not fairly represent the state of the case: the Company was, in fact, formed primarily to hold the Lane Fox patents; and the nominal capital of £100 was merely registered for the purpose of apportioning the respective interests of certain individuals. You further state that we have 'now realised that there is no hope of a simple recognition of the patents.' The original scheme, with which we started, was undoubtedly to make an experiment in the direction of obtaining a recognition, without a show of force, and before negotiations were entered into for raising an adequate working capital. Although for a time our negotiations had almost come to a 'dead lock,' I may say, that owing to circumstances that have since arisen, we have not even now wholly abandoned the hope of obtaining a voluntary recognition of the patents without capital outlay. At present, it is true that we 'are not prepared to make a test case;' but negotiations are in progress, about which I can say nothing at the moment, which may have the effect of wholly altering the situation in this respect. Doubtless, as you suggest, our original policy will undergo considerable change, and, indeed, we are fully prepared so to modify it as to meet any requirements that may be brought home to us in the development of the situation."

Metallic Circuits for Telephones.—Several telephone companies in the United States, according to the *Electrical News* of Toronto, are seeking legislation to compel the railroads to discontinue the use of the earth as a return conductor, claiming that they were there first. Suits have been brought in several Courts, and the results have been various. In most of the decisions the electric railroads have been sustained. Most of the trouble can be eliminated by the use of a metallic return wire for the telephones, and this is being adopted by many of the companies as a temporary remedy. This will not only eliminate disturbances caused by electric light and railroad induction, but also the thousand and one frying, fizzling, and rattling noises, caused by battery wires, telegraph signals, earth

Digitized by Google

currents, atmospheric disturbances, &c. Companies will see it is to their interest to provide their customers with a quiet line at all times, though the expense may at first be considerrable. One of the telephone companies in Montreal use this system with complete success, though the wires in many cases run directly upon the electric light companies' poles.

Unsuccessful Gas Opposition.—The Scottish House-to-House Electricity Company (Limited) having obtained a Provisional Order for the electric lighting of Coatbridge, the Committee of the House of Commons, on the 18th., had before them a Bill for the confirmation by Parliament of that Order. The Coatbridge Gas Company appeared to oppose the confirmation of the Order on the ground that there was no demand for electric lighting in the locality, but if an Order was to be issued it should be given only to the gas company. Evidence was given on behalf of the promoters by Bailie Crawford, of Glasgow; Mr. R. G. Mitchell, burgh engineer, Coatbridge; Mr. Angus Macleod, Glasgow; and the secretary of the applicant company. There were examined on behalf of the gas company the chairman, the manager, one of the Directors, and a London gas engineer. Mr. Pope, Q.C., and Mr. Baggallay having addressed the Committee on behalf of the promoters, and Mr. Balfour Browne, Q.C., on behalf of the gas company, the room was cleared; and the Committee, after considering the matter, intimated that they unanimously confirmed the Provisional Order. This being the first case in which a Provisional Order has been opposed by a gas company on the ground of competition is likely to form an important precedent and to regulate Parliamentary practice in the future.

The Effect of Electricity on the Coefficient of Friction.—On account of the variance of opinion on the several experimenters in this line of investigation, Mr. M. Levy, of Cornell University, applied himself to obtaining data. The apparatus used in these experiments consisted chiefly of an iron plate resting in a perfectly horizontal position on the periphery of three cast-iron wheels, the latter restricted to turning except in one direction. If not prevented the plate would therefore take up the same direction and rate of motion as the point at the periphery of the wheel in contact with the plate. This tendency of the plate to move, caused solely by the friction between the wheel and plate, was measured by suitable apparatus. Proper measurements were taken when currents varying from zero to 47 amperes passed between the surface of contact of the wheels and plate. With perfectly clean and dry surfaces of contact and about 45 amperes passing, an increase in the coefficient of friction amounting to about 119 per cent. was observed. When the surfaces of contact were bathed in oil 40 amperes increased the coefficient of friction by almost 108 per cent. With a thin coating of oil 47 amperes increased the coefficient 133 per cent. Up to 41 amperes water seemed to prevent the above observed effect of the current. A current of 40 amperes through the surface of contact of wheels and plate corresponds to a current-density of no less than 5,000 amperes per square inch.

The Thunderstorm.—The storm which was raging as we went to press last week was more remarkable for the rainfall than for damage done by lightning. At Stanmore 2·91 inches of rain were recorded in 12 hours. The flagstaff over the Free Library at Southampton was struck by lightning and much splintered. The shock of the electric discharge shook the building, and for a short time there was something like a panic in the reading-room. A tradesman standing at his door at the time noticed the lightning descend, as though in a ball of fire, from the flagstaff towards the centre window of the Library, and then disperse in the air with a loud report. During the thunderstorm a curious accident occurred at Freemantle, in a house in Nelson-road. According to a local paper the lightning got under the roof, stripped a considerable portion of it off and knocked off several chimney-pots. Passing down one of the chimneys leading to the living-room, the electric fluid lifted the kitchen range right out into the centre of the room. At the Common Room, Lincoln's Inn, a boy's hand resting on the speaking tube was knocked away and hurt, but was not marked. There was no reverberation, but a sharp crack, simultaneous with the flash, like the explosion of a gigantic copper gun-cap; and the only damage done was the splitting of a portion of a gaspipe in the basement, the soft metal melting and falling in splashes on the floor. The gas was ignited at the fissure. Had not the steward, with commendable promptitude, turned off the gas at the meter a fire would have occurred. At Longham, in the New Forest, three farm labourers took shelter from the storm under a tree, and one of them was killed by the lightning.

The Telephone in Kent.—The Kent County Council have had notification given to them by the South of England Telephone Company (Limited) of an intention to erect trunk communication between Sittingbourne and Maidstone to connect Maidstone with the East Kent system, and between Ashford, Bennington Lees, Challock Hill, Moldash and Chilham and also between Teynham and Sittingbourne. The committee, who have considered the application as a basis for future guidance, have drawn up the following rules:—(1.) That a rent of £1 per mile of the system be paid to the county. (2.) That the poles and wires be removed upon three months' notice being given by the Council. (3.) That all present or future county buildings and offices of county officers along or near the line of telephone will whenever practicable be connected with the Company's system, and suitable instruments kept in efficient working order, free of cost to the county, and that no rent be charged for the user by or on behalf of the county for the same. (4.) That any damage done in the construction or maintenance of the work be made good by the applicants, who shall also be made to undertake the entire liability of any damage or injury to property or to any persons that may result from defect or breakage or any other cause. The approval of the County Surveyor to be obtained as to the position of the poles before the same are erected, and no struts or straining wires to be permitted beyond the face of the poles. —These conditions having been adopted at a meeting of the Council they will become part of the county's bye-laws. It has been stated that the Telephone Company has no objection to these conditions, or otherwise some of the members of the County Council would not have agreed to charging the rental, they being of opinion that everything should be done to facilitate telephonic communication.

Municipal Control of Electric Lighting in America.—There seems to be a difference of opinion as to the relative advantages of electric lighting by municipal authorities or by private companies in the United States. Mr. M. J. Fancises, writing to the *Electrical Engineer* of New York, June 25, combats the views set forth in a previous issue of that journal by Mr. Rosewater, of Johns Hopkins University. He says that the latter claims that hired politicians, whose tenure of office is but for one year, without experience or knowledge of the business and with no financial interest in it, with the exception of their salaries, will give the tax-payer better service than the private corporation. The manager of an electric light company, however, is personally interested, and knows that its success depends upon his furnishing the best service at fair rates. Now, in order to accomplish this, it is evident that he will bring to his aid all that years of experience have taught him is best in electrical apparatus, together with the latest inventions and improvements. Several cities owning plants, having found by actual experience that the service and expenses relating to the same were unsatisfactory, are now considering the advisability of abandoning the control of the plant, and are negotiating for contracts with electric light companies to light their streets. Philadelphia, owning an immense gas plant, which Mr. Rosewater says the "Select Council were wonderfully pleased with, because they were making a profit," has contracted with electric light companies to light the streets for $177 per year each lamp, or more than three times the amount he claims as the average cost for those cities producing their own lights. The taxpayers of Philadelphia have had an experience with both plants, and evidently think any price a private corporation will offer is cheaper and better than municipal control. Hypothesis and theory may do on paper, but actual results obtained by practical application and experience are the only reliable data upon which to base any statement relating to the cost of street lighting. In every case these have shown, where all the facts are given, that it has been for the best interest of the citizens and taxpayers to contract with an electric light company for lighting the streets of any city.

MAGNETISM IN IRON AND OTHER METALS.*—XXIV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 251.*)

§ 91. **Magnetisation in Strong Fields.**—We pass now to speak of the opposite extreme of the magnetising process. In studying the relation of magnetism to magnetising force by any of the methods which have been described in earlier chapters, it is scarcely practicable to raise the force H beyond a few hundreds of C.-G.-S. units at the most. Formidable difficulties present themselves, the chief of which comes from the heating effect of the magnetising coil. Special methods have therefore to be resorted to when we wish to examine the behaviour of iron or other magnetic metal in very strong fields.

It is true that the most important parts of the magnetising process lie within the range of those forces which may easily be produced by means of a magnetising coil. Within that range the permeability or the susceptibility passes through its great changes, increasing quickly from a small finite initial value to a maximum ten or fifteen times as great, and decreasing almost as quickly to a value smaller than the first. Within that range, too, the residual magnetism apparently reaches the full value it is capable of reaching. It is within that range that the most prominent features in the influence of vibration, of temperature, and of stress, manifest themselves. And it is probably true that whatever knowledge of magnetic quality is wanted for application to the practical ends of electrical engineering can be obtained by experiments within that range.

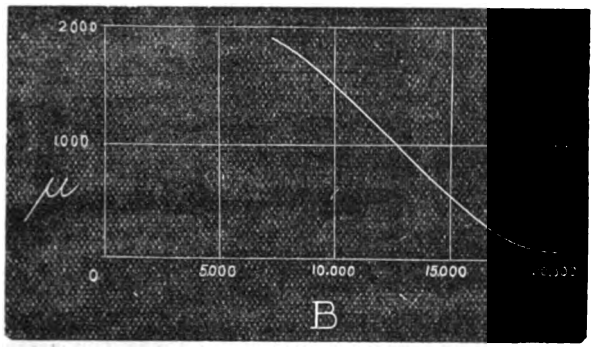

FIG. 63.—Permeability of Wrought Iron when strongly magnetised.

But still the action of stronger fields is of very great interest, especially in relation to the molecular theory of magnetism propounded by Weber. According to Weber's theory the molecules of iron or any other magnetisable metal are always magnets. These point anyhow in the unmagnetised piece, so that the sum of their moments, resolved in any direction, amounts to zero, and the piece, therefore, has no magnetism as a whole. But when a magnetising force acts the molecular magnets tend to turn, so that their axes point more nearly in the direction in which the force acts; and thus the piece, as a whole, becomes a magnet. The intensity of magnetisation I is the sum (per unit of volume) of the moments of the molecular magnets resolved in the direction of the magnetising force. We shall discuss this theory more fully in a later chapter. Meanwhile, one obvious deduction from it may be pointed out. When all the molecular magnets are turned round to face exactly in the direction in which the force acts, no further magnetisation in that direction will be possible, however much the force may be increased. In other words, the theory points to this—that the intensity of magnetisation I has a saturation value which cannot be exceeded, though it points to no limit to the value which B, the magnetic induction, may reach.

In experiments made with moderately strong magnetising forces both B and I are increasing slowly at the last; and it is impossible to infer, from the results of such experiments, whether B or I or either of them is approaching a finite limit. The curves of permeability or of susceptibility in relation to B or to I (such as have been given in Figs. 40, 41, and 42) do not help us to a conclusion; we cannot produce a curve of this kind beyond the region of experiment until it cuts the axis of B or of I, because (as Figs. 41 and 42 show) the curve bends out when the magnetising force is sufficiently increased. This characteristic of the curve of κ and I or of μ and B was first pointed out by Fromme,* and has been commented on by a number of other experimenters. In some of the writer's experiments it appeared when B exceeded about 15,000.† Figures given by Bosanquet‡ for experiments with iron and steel rings, in one of which the induction was pushed as high as 19,300, show when plotted a similar inflexion in the curve of μ and B occurring when B is about 15,000. The same feature is well shown in Fig. 63, which is copied from a Paper by Bidwell,§ describing experiments with soft wrought iron, in which the induction was raised to 19,820, with the result of reducing μ to 33·9. To produce this the force H was 585, and the resulting magnetisation I was 1,530. These numbers give some idea of the extent to which experience has shown it is practicable to go in experiments of the ordinary class, using the magnetising force of a current in a coil.‖ To answer the question whether there is any finite limit to I or to B, we have to go far beyond this range.

§ 92. **The Isthmus Method.**—This name has been given to a method introduced in 1887 by the writer and Mr. W. Low,¶ which has allowed the magnetisation of iron to be raised to greatly higher values, with the result of showing that, while B has apparently no limit, there is a finite limit to I, as Weber's molecular theory predicts.

In the air-space between the pole-pieces of a strong electromagnet, we have a magnetic field of much greater intensity than any that can easily be produced by the direct action of the electric current. If a small test piece of the metal which is to be magnetised be placed across this space, so that it forms an isthmus between the two pole-pieces, it will become strongly magnetised. In becoming magnetised, however, it disturbs this field, and the force acting on it may be very different from the force which existed in the empty space. If it is a short cylinder extending lengthways from pole-piece to pole-piece, its magnetism will be very unequal. At the ends the induction will have the same value as it has in the pole-pieces themselves; at the middle it will be stronger, owing to the convergence of lines of induction from neighbouring parts of the pole-pieces, which find their way into the test-piece through its sides. Evidently we may increase the induction in the middle by furnishing the specimen with spreading ends, which will present an easier path along which the lines of induction may converge. Moreover, when the test-piece takes the form of a bobbin, with a short, narrow, central neck from each end of which a cone extends, spreading over the face of the pole-piece, it becomes possible (by giving a proper form to the cone) to secure that the central neck will be uniformly magnetised, and that the magnetic force which acts on it will have the same value as the magnetic force in the immediately surrounding air-space. The magnetic force and the magnetic induction within the neck then admit of being measured, and the permeability, susceptibility, and intensity of magnetisation under exceedingly strong forces are readily deduced.

§ 93. **Early Experiments, using the Isthmus Method.**—Figs. 64 and 65 show two forms of bobbin which were used in the first application of the isthmus method. The dimensions are marked in millimetres. The central neck was wound with an induction coil consisting of a single layer of fine wire, and its magnetism was measured by the ballistic method. With bobbins of the shape shown in Fig. 64, the induction was measured by suddenly slipping the bobbin out from its place between the pole pieces while the electro-magnet was excited. An

‖ In recent experiments by du Bois, described in § 107 below, a coil was used to produce magnetic forces which ranged up to 1,300 C.-G.-S.

¶ *Proc.* Roy. Soc., March 24, 1887.

Digitized by Google

objection to this is that it takes no direct account of the residual induction; it shows only the magnetism that is lost when the bobbin is withdrawn from the field. The residue is small, and it may be separately measured and allowed for; but a better arrangement is shown in Fig. 65, where the bobbin may be turned suddenly round so that its magnetism is reversed; half the ballistic effect of this reversal of course measures the magnetic induction. To measure the field in the air-space immediately surrounding the neck, a second induction coil was wound over the first, but at a little distance from it, so that a narrow ring of non-magnetic space—about 1·3mm. wide—was included between the two. The magnetic force in this space was calculated from the observed difference in the ballistic

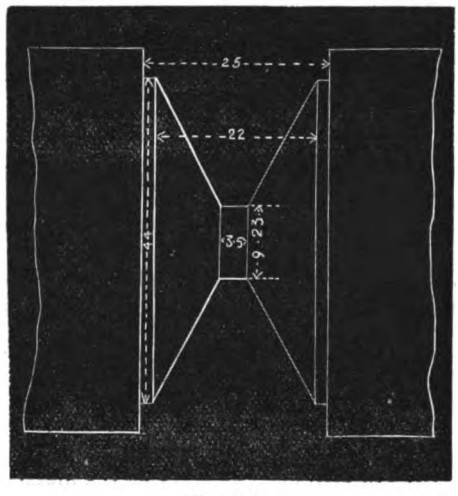

Fig. 64.

effects of the inner and outer coil. The knowledge of it allowed a proper correction to be made, by which the whole induction within the inner coil was reduced to allow for those lines of induction which lay within it but not within the iron.

With the bobbins shown in Figs. 64 and 65 the outside field —that is to say, the magnetic force in this narrow ring of space surrounding the neck—was probably a very little stronger than the mean force within the metal of the neck itself. Still, the

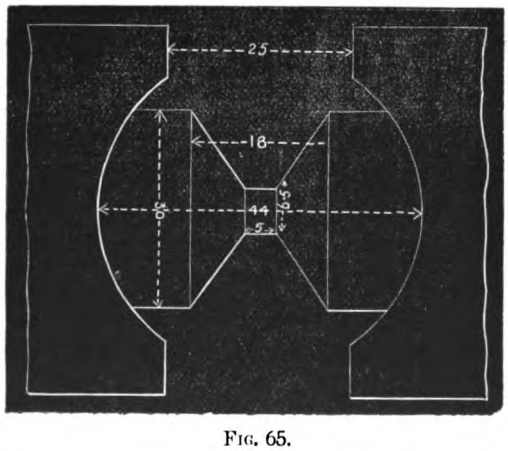

Fig. 65.

outside field was so nearly equal to **H**, that the quantity $\frac{\mathbf{B} - \text{outside field}}{4\pi}$ approximated closely to the value of **I**, and the quantity $\frac{\mathbf{B}}{\text{outside field}}$ approximated closely to the value of the permeability, μ.

The results in Table VIII. were obtained with a bobbin of soft Swedish wrought iron in the annealed state.

These figures show that in the very strong fields with which this experiment deals, the quantity in the third column, which is approximately equal to the intensity of magnetisation **I**, becomes practically constant. Such variations as occur in the numbers are irregular and come from errors of observation. The iron is here in a condition of true saturation; **I** has reached a value which refuses to undergo any sensible increase, though the strength of the field be doubled; but the field itself may be increased without limit, and consequently there is no sign of any limit to the value of **B**.

Table VIII.—*Swedish Wrought Iron in Strong Fields.*

Outside field (=**H** nearly).	**B**	$\frac{\mathbf{B} - \text{outside field}}{4\pi}$ (=**I** nearly).	$\frac{\mathbf{B}}{\text{outside field}}$ (=μ nearly).
6,690	27,960	1700	4·18
8,900	29,730	1660	3·34
9,510	30,820	1700	3·24
10,000	31,210	1690	3·12
10,360	31,630	1700	3·05
10,810	31,720	1670	2·94
10,880	32,060	1690	2·95
11,200	32,360	1690	2·90

Table IX. gives the results of a similar experiment made with a bobbin of annealed Lowmoor wrought iron, and with a wider range of magnetic forces. The apparent decrease of **I** in the strongest field, which is shown by the last numbers in the third column, is due to the fact that the outside field was rather greater than the true magnetic force within the metal. When the bobbin is so shaped that this source of error is avoided, the apparent decrease disappears, and **I** is then found to be as nearly constant as casual errors of observation allow it to be.

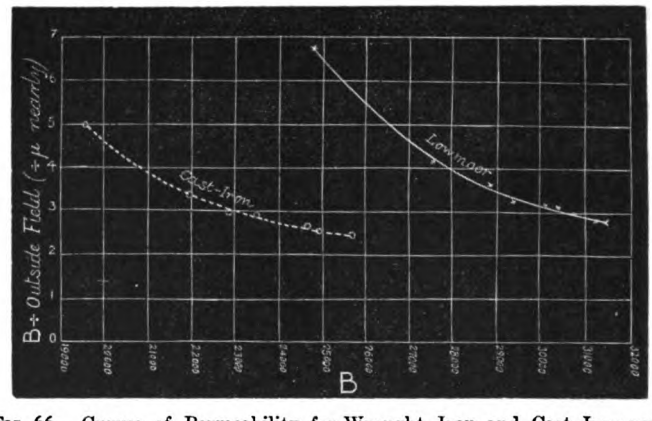

Fig. 66.—Curves of Permeability for Wrought Iron and Cast Iron very strongly magnetised.

A noticeable feature in these results is the reduction of the permeability that is brought about by continuing to increase the magnetising force after a state of saturation has been reached. With wrought iron such as was used here the initial value of μ for exceedingly small forces is nearly 200; and the maximum of μ, reached generally with a magnetising force of two or three units, may be as much as 3,000. Here, with a magnetising force of 10,000 units or so, μ has fallen to less than 3.

(To be continued.)

VERIFICATION OF OHM'S LAW.

In one of the Circulars issued to the Electrolysis Committee of the British Association, viz., that dated June 24, 1886, Prof. Fitzgerald suggested an objection to the complete validity of the theory of the experimental mothod of verifying Ohm's law with twelve-figure accuracy, devised by Clerk Maxwell, and carried out by Mr. Chrystal; doing so in the following words:—

"There is an objection to this method that I have not seen noticed. Maxwell assumes that you can expand in powers of $\frac{C^2}{S^2}$. Now, if the law were the positive value of $\left(\frac{C}{S}\right)^n$ where n differs very slightly from unity, the method would fail, for the current would vanish both in the numerator and in the denominator of Maxwell's expansion."

Maxwell's Theory is given in the Glasgow volume of the British Association for 1876.

Recently Dr. Fison seems to have promulgated the same objection, and consequently Prof. Fitzgerald wrote to Prof. Chrystal about it. In reply he received a very interesting letter, which he has passed on to me, and from which I extract the portion referring to this subject, sending it herewith for publication. OLIVER J. LODGE.

Letter from Prof. Chrystal to Prof. Fitzgerald.

. . . The problem which I set myself in the Ohm's law experiment was to show that when a Wheatstone's bridge is balanced for any electromotive force in the battery circuit, it is balanced for every, or, to put it safely, for widely varying electromotive force.

The theoretical part of the Paper, for which Maxwell was responsible, I do not remember ever having examined from a sceptical or logical point of view.

It now appears to me that we ought to reason as follows:—

In order to find the necessary condition upon the resistance-function E C, let us make matters as simple as possible by considering a bridge in which two arms, R, R, are of equal resistance, of the same metal, and *alike in every respect*. Let the two other resistances S and T be made of two different metals, say of Cu and Fe. Let the length and section of S be l and ω; and the length and section of T be l' and ω'. The specific resistance must in each case be a function of the current intensity (current per unit of section). Temperature is supposed kept constant, of course. Let the whole current flowing through S and T when there is balance be i, the specific resistances of S and T will be $\phi(i/\omega)$ and $\psi(i/\omega')$ respectively.

The condition for balance will therefore be

$$(l/\omega)\,\phi(i/\omega) = (l'/\omega')\,\psi(i/\omega') \quad . \quad . \quad . \quad . \quad (1);$$

and this equation must, by the result of the experiment, *hold for all values of i*.

Let us suppose that we alter the length of the iron wire S to l'', then there will be a corresponding section ω'', for which there will again be a balance; so that we must have

$$(l''/\omega'')\,\phi(i/\omega'') = (l'/\omega')\,\psi(i/\omega') \quad . \quad . \quad . \quad . \quad (2);$$

and this again must hold for all values of i.

Combining (1) and (2) we get

$$(l/\omega)\,\phi(i/\omega) = (l''/\omega'')\,\phi(i/\omega'') \quad . \quad . \quad . \quad . \quad 3)$$

From this equation we can readily determine the form of the function ϕ.

If we put $\mu = \omega''/\omega$, $\lambda = l''\omega''/l\omega$ $x = i/\omega''$, we get

$$\phi(\mu x) = \lambda\,\phi(x);$$

whence, putting $x = \mu x$, we get

$$\phi(\mu^2 x) = \lambda\,\phi(\mu x) = \lambda^2\phi(x);$$
$$\phi(\mu^3 x) = \lambda^3\phi(x);$$

and, in general,

$$\phi(\mu^n x) = \lambda^n\phi(x).$$

Hence, putting $x = 1$, we get

$$\phi(\mu^n) = \lambda^n\phi(1).$$

Now μ is unrestricted, therefore we may put

$$z = \mu^n, \quad n = \log z/\log\mu.$$

Whence, finally,

$$\phi(z) = \lambda^{\log z/\log\mu}\phi(1).$$
$$= z^{\log\lambda/\log\mu}\phi(1).$$

The general form for $\phi(z)$ is, therefore,

$$\phi(z) = A\,z^B,$$

where A and B are constants, the physical meanings of which are obvious from what precedes.

We see from equation (1) that the like holds for the specific resistance of every metal which has the property indicated by the experiment.

Moreover, as you have pointed out, such a law of specific resistance is sufficient to secure the result of the experiment.

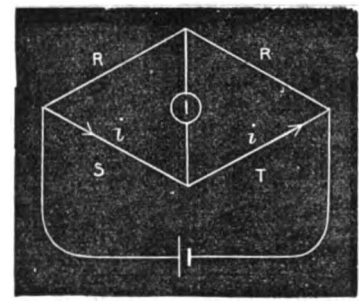

FIG. 1.

We conclude, therefore, that what the experiment really proves is that the specific resistance of metals varies as a power of the current intensity, *which power is the same for all metals*. This is a good deal, but not quite so much as is concluded in the Paper in which the experiment was originally described. The deviation spoken of in the Paper must, therefore, be regarded as deviations not from *absolutely constant resistance*, but from the *resistance calculated according to the above simple law*.

To establish that the constant B is zero will not be quite so simple a matter. Many ways might be suggested, and will, doubtless, occur to you. The most direct and satisfactory would be to get the resistance for different current-intensities, in Joule's way, by measuring the heat evolved.

Should the above sophistry be right, it is curious that you and Dr. Fison should each have suggested not *a way*, but *the only possible way* in which the resistance may vary with the current, and Wheatstone's bridge still remain the ideal instrument that electricians have always considered it to be. G. CHRYSTAL.

OBSERVATIONS ON CURRENTS ORIGINATING IN ORDINARY AERIAL TELEGRAPH CONDUCTORS.*

BY A. R. BENNETT, M.I.E.E.

All users of telephones connected by single wires are familiar with the variety of noises which are generally present, even when the line is only a few hundred yards long. It is exceptional to find a wire which can be said to be even approximately silent at all times. The origins of some of the foreign currents which the presence of these noises indicates have been explained by Preece, Lockwood, and others. Recently in testing some overhead copper and iron wires run on the same poles for capacity by charge and

* Paper read at the special meeting of the Institution of Electrical Engineers, held at the Edinburgh International Exhibition, July 15, 1890.

Digitized by Google

discharge, using a sensitive reflecting galvanometer, the author noticed the presence of currents which could not be accounted for by any of the known explanations, and the causes of which he determined to investigate.

It was noticed that soon after the commencement of rain, a steady current appeared on all the wires under test. The deflections increased as the rain continued, until, after the thorough soaking consequent on several days' wet, they were in some case no longer within range of the scale. A constant discrepancy in the behaviour of copper and iron wires was apparent. The deflections from the copper were always positive, while those from the iron were always negative, and invariably much feebler, seldom exceeding one-third the strength of the positive ones.

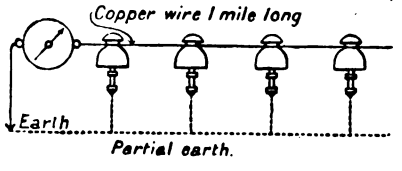

FIG. 1.

To ascertain the cause, two wires, one No. 12½ copper and the other No. 11 galvanised iron, run side by side on the same arms for the distance of a mile (Fig. 4), were taken. In fine weather the insulation resistance of each was infinite.

When disconnected at the further ends and earthed at the home end through the reflecting galvanometer (Fig. 1.), they always in wet weather exhibited the phenomena described.

The following are extracts from the records of tests, extending over several months, during medium and heavy rain :—

Copper (always positive).		Iron (always negative).	
Degrees.	Value of deflections in milliamperes.	Degrees.	Value of deflections in milliamperes.
4·5	·0030375	1·5	·0010125
13·0	·008775	3·75	·00253125
20·5	·0138375	4·0	·002700
17·0	·011475	3·0	·002025
15·0	·010125	4·5	·0030375
3·0	·000025	17·5	·0003375
46·0	·031050	17·5	·0118125
22·0	·014850	7·0	·004725
14·5	·0097875	3·5	·0023625

It will be observed that the copper deflections were always from three to six times stronger than the iron ones. When the copper

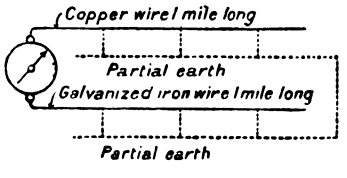

FIG. 2.

and iron wires were left insulated at their distant ends, and looped through the galvanometer (Fig. 2), earth being excluded, the positive and negative deflections were always equal. Thus, taking the last three of the foregoing tests, when looped 46+17·5− became 35+35−; 22+7− became 12·5+12·5−; 14·5+3·5− became 9·7+9·7−.

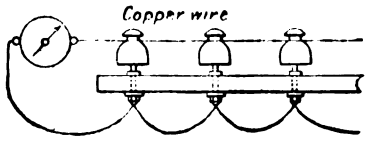

FIG. 3.

Half-a-dozen insulators, with galvanised iron bolts, were mounted on an arm in the testing-room, and thoroughly wetted (Fig. 3). With a copper wire run on them, and the bolts connected as shown, a positive current appeared as soon as a film of water was established between the wire and the bolt. With an iron wire instead of the copper no current appeared. The positive current, therefore, seemed to be due to voltaic action between the copper wire on the insulators and the galvanised iron bolts supporting them when connected with the moist surface. The course of the current can be traced in Fig. 1. The wire and insulator bolts form a series of voltaic cells joined in parallel.

The absence of a current from the iron when mounted on the experimental arm confirmed this conclusion, since no current was to be expected under the conditions. But whence then the negative current from the iron wire run on the actual poles? In that case it had a copper wire strung alongside it (Fig. 4). The wetting of both insulators established the connection necessary for electrolytic conduction between them, so that the metals constituted a voltaic couple, the negative current from which appeared on the iron.

The positive current on the copper was consequently due to the copper wire acting with the iron bolts of its own insulators, the iron bolts of the neighbouring insulators and the iron wire which they supported.

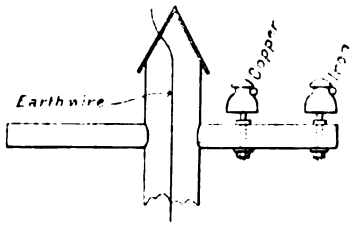

FIG. 4.

The negative current on the iron was due to the iron wire, its bolts and the bolts of the neighbouring insulators acting with the copper wire. But the bolts of the insulators (Fig. 4) were partially earthed by the damp wood of the poles and the earth wires which ran down them. If the earth had been perfect no current could have got to the galvanometer, but since it was only partial some found its way by that route; and so the difference in strength between the positive and negative currents is accounted for.

The positive, depending chiefly on the action between the copper wire and its own bolts, between which no earth intervenes, is necessarily stronger than the negative, which depends wholly on the action between the iron wire and bolts and the copper wire between which a partial earth is interposed (Fig. 5). So when the earth is cut off from the galvanometer (Fig. 2) the effect of the earth between the two plates is neutralised, and the positive and negative deflections become equal.

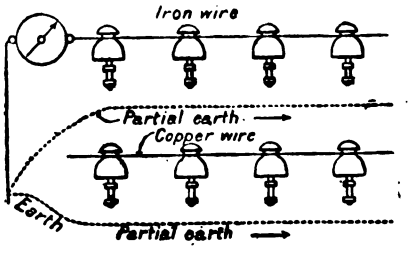

FIG. 5.

A somewhat unexpected effect of the recent introduction of copper wires for telegraph and telephone purposes is consequently the establishment over the country of a vast number of voltaic couples, which only become operative in damp or wet weather.

The zinc of the bolts of insulators carrying copper and bronze wires may reasonably be expected to disappear sooner than in days gone by when only iron wire was used; and when copper and iron wires are run on the same poles the galvanising of the iron must suffer sooner than of yore.

The Americans, with their wooden pins, will escape the currents due to the difference of metal between the wire and its supports: but when they mix wires of different metals on the same poles the resulting action will be stronger than with us, since they do not earth-wire their posts. Telephonically, the existence of these currents is of little moment. With metallic loops, when both wires are of the same metal, they will not matter at all, since the currents from two similar wires will be in the same direction and of the same strength, and, meeting in the telephone or translator, will neutralise one another.

On single wires, so long as the currents remain steady, their presence does not matter much. As they increase gradually as the insulators become wet, and die away slowly as they dry, they do

Digitized by Google

not give rise to any disturbance in the telephone. If any confirmation of the voltaic origin of these currents were needed, it would be afforded in the fact that it is possible, by charging the line from a battery, to polarize the line couple even to the extent of obtaining temporary currents of the opposite sign. Thus, the copper was repeatedly charged from a 90-volt battery; when from the positive pole the line current was increased, when from the negative the line current was decreased and sometimes reversed.

The following are particulars of several tests of the copper wire, the deflections being in degrees:—

Charging Wire from 90 volts, – to line, so as to neutralise and overcome Line Current.

Line current.	Duration of charge.	Result.
·5+	10 seconds	Reversed to ·2–
6° +	20 „	Reduced to 5·0+
8·4+	4 minutes	„ „ 3·5+
12·5+	10 seconds	Reversed to ·2–
	Spot went back instantly to ·5+, and then recovered slowly to 12·5+.	
12·5+	20 seconds	Reversed to ·4–
	Went backly quickly at first, and then slowly recovered to 12·5+ in 45 seconds.	
12·5+	1 minute	Reversed to ·8–
	Went back instantly to 3·5+, recovering slowly to 12·5+ in 70 seconds.	
12·5+	2 minutes	Same as 1 minute
12·5+	3 „	„ „

The same effects were produced with the experimental arm. With only one insulator, reversed, the cup being full of water and the surface well wetted, a deflection was got of 4deg., equal to ·0027 milliamperes. When the current from this insulator was reduced to ·2+ through the surface drying, a reversal could always be obtained to ·4–, and sometimes to 6·– by charging it from 90 volts.

During the capacity tests already mentioned, it was observed that for some time after the commencement of rain, the apparent capacity of the wire invariably rose instead of falling with the decrease of insulation. This effect has, of course, been noticed before; but as the author was not aware that it had been satisfactorily accounted for, it was resolved to investigate, and the result of the investigation seems to point to several contributory causes. Firstly, no doubt, the line current due to the voltaic action already described will increase or diminish the discharge according to the direction of the charging current. Secondly, the polarisation of the bolts due to the charging current will have the same tendency. But the capacity of the line will appear too high when the moisture on the insulators is too slight to permit of voltaic action. To seek the cause of this, 12 feet of copper wire was run on six dry insulators, fixed in oaken arms in the test-room. With 90 volts the wire gave a discharge of ·4deg. The tops of the insulators around the binding wire were wiped with a wet sponge. The discharge then rose to 1deg., more than double. Wetting more of the surface of the insulators resulted in a still further increase. Several discharges could be got without renewing the battery charge. It would, therefore, appear that wetting the insulators is equivalent to an increase of conductor surface. The moisture has to be charged as well as the wire, and the consequent discharge is greater than with a dry wire. The effect is only observable in moderate rain or for some little time after the commencement of heavy rain; when the insulators become thoroughly wet, the insulation and the capacity fall together, and then the voltaic action and polarisation come into play, together with another phenomenon which has not yet been referred to.

Incidentally, in the course of these tests, it was found that when a wire is in contact with moist wood, and is charged from a powerful battery (90 volts were used) the discharge is several times stronger than when the same wire is supported on dry or partially moist insulators. Thus a length of wire on insulators gave a discharge of ·9deg.; when stapled along an oaken arm not sensibly damp, the discharges, after 20sec. charge, amounted to 4·5deg., and after 80sec., to 5deg. Then a residual charge appeared to remain in the wood, as the wire continued to yield a current of ·5deg. for some minutes, then gradually dying away to nothing. Many tests, varied in details, gave the same results; 30ft. of wire in air gave a discharge of ·4deg. When the same wire was stapled on a deal board (Fig. 6) not sensibly damp, with staples of the same metal as the wire, the discharge became 3·5deg., falling immediately to 1deg., and then slowly to zero. The wire and the wood were then sponged, and the discharge rose to 7deg., falling immediately to 2deg., and returning slowly to zero. The wire yielded a series of smaller discharges for several minutes without any fresh contact with the battery. A deal box wetted, having some bronze wire in contact with it, was well insulated by being suspended by G. P. Charged for 20sec. from 90 volts, it gave a discharge of 1·6deg., sinking immediately to ·8deg., and then gradually to zero. The same box standing on the floor, gave a discharge, under the same conditions, of 12deg., sinking to three degrees, and then slowly to zero. The same box touched by the end of an earth wire—also of bronze—well away from the bronze wire, gave a discharge of 45 degrees, sinking immediately to 26 degrees, and thereafter slowly to zero. In the two first cases only one metallic conductor, that is to say, the bronze, through which the charge was communicated, was present, and the source of the return current is not very apparent.

The last case closely resembles that of a wet telegraph pole, the earth-wire of which does not touch the bolts. Then an expanse of wet wood intervenes between the bolts and the earth, and a powerful charging current in the line must, with leaky insulators, result in back currents. As it is evident that moisture in wood has the effect of increasing the capacity, it may not be unreasonable to deduce that moisture in the air surrounding the wire may have the same effect.*

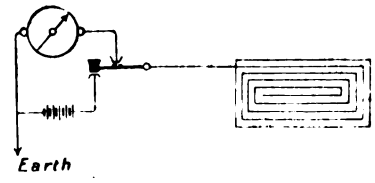

Fig. 6.

The foregoing particulars apply whether the line is of copper or of iron. The following observation applies to iron alone. It has been mentioned that no current between a galvanised iron wire on a wet insulator and the bolt could be detected. But if such a wire is charged by 90 volts, the discharge is followed by a counter-current from the insulator. The effect can be produced with a few inches of galvanised iron wire and a wet insulator, as in A, Fig. 7. Charging such an arrangement by 90 volts yielded a discharge of ·4 degrees and a counter-current of ·3 degrees, which did not wholly disappear for some three minutes. Obviously, the polarisation of the bolt following on electrolysis of the moisture made the insulator a secondary battery. The effect of damp wood may be markedly shown by shifting the return wire to the bolt of an adjoining insulator, as in B, Fig. 7. The discharge then became 1·5 degrees and the counter-current 1 degree, an augmentation of nearly four times. Connecting the earth-wire direct to the bolts will obviate the effect of moist wood, but it increases the strength of the voltaic action and the polarisation of bolts by the charging current.

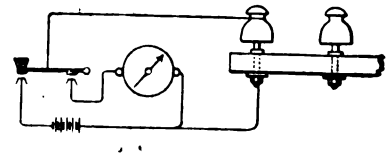

Fig. 7A.

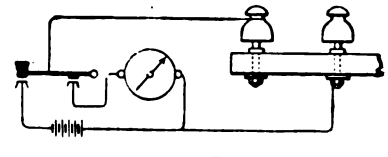

Fig. 7B.

Although the Americans escape the voltaic action consequent on the use of metallic bolts, the damp wood of their poles cannot be without its effect in wet weather with the insulators they use.

The current set up between copper wire and iron bolts in wet weather might be used to signal with. The experiment has not been tried; but it seems plain that a galvanometer at A, Fig. 8, through which the line current circulates in its full strength when the wire is insulated at B, would be affected by the working of a

* Note.—Since reading the Paper it has occurred to the author that the probability of this conclusion is strengthened by considering that dry and moist air have very different capacities for heat. Tyndall found that the absorption of heat by dry air being 1, that of the air of his laboratory, not specially damp, was 72, while that of air designedly moistened was no less than 90. Thermal and electrical vibrations differ only in frequency, so that some common absorptive action in respect to air may be looked for. The heat absorbed by the moisture in the air is, after the withdrawal of the source of heat, radiated or discharged, not instantly but gradually; just as the electrical charge, after the cutting off of the battery, is parted with slowly and by degrees, as indicated by the residual charge. It may be expected, therefore, that the apparent capacity of a conductor will be least when contained in artificially dried air.

Digitized by Google

key between the line and earth at B; for the key, when closed, would shunt a large proportion of the current away from the galvanometer.

It will be observed that these experiments were made with the distant ends insulated—a condition which does not obtain in ordinary telegraphy. The practical effect of the disturbances noted

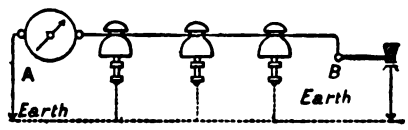

Fig. 8.

may be insignificant, especially with the double-current working, but still it is well to know that they exist.

[The discussion which followed the reading of this Paper will appear next week.]

SOME EXPERIMENTS UPON ALTERNATING-CURRENT APPARATUS.*

BY HARRIS J. RYAN.

It is well known that when the core of a transformer is heated under certain favourable conditions, the secondary will deliver electrical energy in amount considerably greater than when the core is not heated; and that this is done, too, without an increase of the energy supplied to the primary. It is stated, in fact, that with a heated core the energy taken up by the primary is less, while that given out by the secondary is greater.

Mr. L. B. Marks, of Cornell University, made an apparatus in which he found this phenomenon very marked; and his experiments are of interest since they indicate the source of energy in the phenomenon observed, and also because they exhibit, in an exaggerated form, certain other phenomena which must be done away with in a transformer that is to be used for incandescent lighting.

The apparatus included a transformer, whose core consisted of well-rusted wire rings, 1·1cm. thick, and of a mean diameter of 17cm. The primary and secondary circuits were wound on opposite parts of the core, and consisted of 500 and 155 turns respective y. The size of bare copper wire in each was No. 18 B. and S. G. The wire was insulated with asbestos paper, and because of its thickness the primary and secondary turns, with their insulation, occupied a space of abnormal proportions. The resistances of the primary and secondary circuits were 1·65 and 0·71 ohms respectively. The maximum intensity of magnetisation used in the core did not exceed 3,000 lines per square cm. The iron core could be heated by means of a gas flame.

The shape of the curves connecting the electromotive forces, and the currents with time, were obtained by a method due to Prof. Ryan, and already described.† The curves obtained are of the same character as those given in Prof. Ryan's Paper already referred to, and are also very similar to those given in Humphrey and Powell's Paper in a recent issue.

Table I.

—	Temp.	Primary E.M.F.	Sec. E.M.F.	Ratio of E.M.F's	Primary watts.	Sec. amps.	Sec. watts.
Secondary open, no heat applied to core	97·5°C.	75·6	16·4	4·6	87·0	0·0	0·0
Secondary open, heat applied to core	300°C.	93·4	24·5	4·0	88·0	0·0	0·0
Secondary closed, no heat applied to core	100°C.	89·3	11·9	8·1	139·0	2·0	24·0
Secondary closed, heat applied to core	270°C.	95·7	13·4	7·1	129·0	2·4	3·67

Table I. gives the particulars of the measurements made on the transformer at various temperatures. The numbers in Table II. have been deduced from those in Table I. by assuming that the loss in the core is proportional to the square of the primary E.M.F., and presumably indicate the results that would have been obtained with 90 volts as the primary E.M.F. in each experiment.

The figures in Table II. show clearly that the loss in the core is greatly diminished when its temperature is elevated, *i.e.*, when heat is applied, and that the loss in the core is practically independent of the output. The result indicates that with the secondary open, and the primary at a difference of potential of 90 volts without heat applied, the core came to a temperature of 97°C., and dissipated 122 watts; while on the application of heat with the Bunsen burner the temperature was raised to 300°C., and only 72 watts were dissipated. Now, if we assume the changes in watts dissipated in the core to be approximately proportional to the changes in temperature that produced the same, we see by estimation that 79 watts would have been dissipated by the core at 270°C., while 80 watts were found to have been dissipated by it at that temperature when the

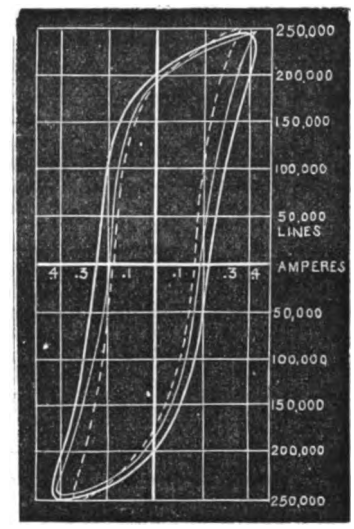

Fig. 1

secondary was closed, and gave an output of 32 watts. Thus, the secondary can be closed and 32 watts abstracted when the temperarure is raised 170deg., while at the same time the number of watts absorbed by the primary is diminished by 5.

The effect must be due to a decrease of the total amount of energy absorbed by the core through Foucault currents and hysteresis. The energy absorbed by eddy currents must be diminished by rise of temperature since the specific resistance is raised; as, however, for decided degrees of magnetism it is known that the permeability of iron increases with rise of temperature, experi-

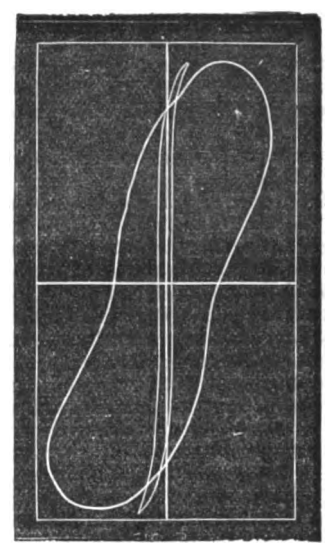

Fig. 2.

nents were made by Mr. A. Herschel to determine the effect of temperature on the hysteresis loss. A cast-iron ring was taken 12·3 cm. in diameter of section and 38·5 cm. in circumference, and wound with 80 turns of No. 8 wire. The highest temperature used was 360°C. The results show that for intensities greater than 3,000 lines the hysteresis loss diminished with rise of temperature, but for intensities smaller than 2,000 no alteration was observed. Now, if wrought iron behaves in a similar manner, the effects observed by Mr. Marks cannot be accounted for wholly or even partly by a diminution in the hysteresis loss, since great magnetic densities were not used. The effects are, therefore, to be entirely

* Abstract of Paper read before the American Institute of Electrical Engineers, June 17, 1890.

† See *Electrician*, January 10, and January 17th, 1890.

Digitized by Google

ascribed to diminution of Foucault currents caused by the change of the resistance of the iron. A liberal estimate for the hysteresis of the core is 20 watts, whence the energy dissipated in Foucault currents by the core at 100°C. and 90 volts was 102 watts, while at 270°C. and 90 volts it was 60 watts. The percentage alteration in the number of watts wasted is very nearly the same as the percentage alteration of resistance for a range of 170°; so that, as it is fair to assume that the electromotive forces are the same for the two cases, and that the watts wasted vary inversely as the resistance, the coincidence affords a satisfactory confirmation.

An interesting feature about Mr. Marks' transformer is that the ratio of the primary and secondary turns was 3·2, while the ratio of the E. M. F. varied from four to eight. The very bad regulation here apparent exhibits in an exaggerated form the trouble it is so hard to get rid of in transformers to be used for incandescent lighting. A large number of the lines due to the primary are not

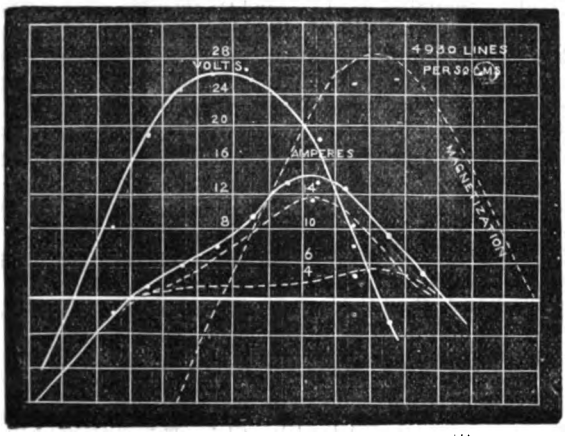

Fig. 3.

enclosed by the secondary, chiefly owing to the large space occupied by the windings. When a current flows in the secondary this effect is greatly increased, and Prof. Ryan shows how to use the curves to separate the active from the leakage magnetisations.

The effect of Foucault currents as distinguished from hysteresis is exhibited in a very striking manner in Figs. 1 and 2. In these curves the inner diagram represents the Ewing's card of static hysteresis, while the outer diagram represents what occurs when both hysteresis and Foucault currents are taken into account. Fig. 1 refers to the 10-light transformer already described (see *The Electrician*, January 10 and 17, 1890). In this case Foucault currents were absent, as the iron circuit was finely laminated and insulated. The outer diagram is deduced from the current and magnetisation curves. For Fig. 2 these curves are shown in Fig. 3.

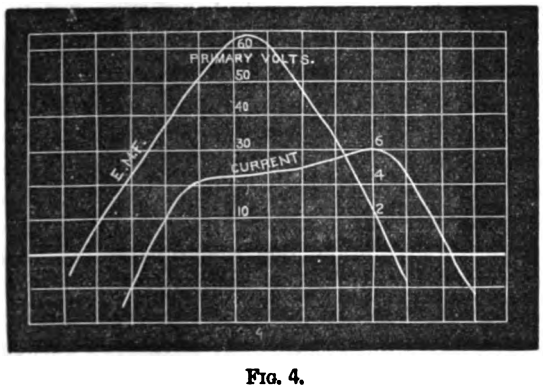

Fig. 4.

The ordinate of the current curve is taken as abscissæ of the new curve, while the corresponding ordinate of the magnetisation curve is taken as the new ordinate. The magnetisation curve is obtained from the E.M.F. curve (*see* Fig. 3) by a graphical process, which is not described.* The curves in Fig. 3 were obtained with 195 reversals per second from a cast-iron ring, 8·6cm. in diameter, and 2·7 square cm. in cross-section, wound with 200 turns of wire of negligible resistance. The lower broken current curve is that of the exciting current curve drawn in from the inner curve of Fig. 2. By subtracting this current from the one that was observed we obtain the upper broken curve, which is the current that exists to supply the Foucault current energy. The point to be noticed about the two extreme cases represented in Figs. 1 and 2 is that in each case the curve of current supplying the Foucault current energy is about one-eighth of a period behind the impressed E.M.F.

Figures 4 and 5 illustrate the extreme variation in the shape of the exciting current curve in going from the lowest to the highest degree of magnetisation. The former illustrates a transformer worked with low magnetic density in the core, while the latter shows the effect of compelling the magnetisation to be carried above the bend of the characteristic curve of the iron.

Messrs. Forhenbaugh and Sawyer, of Cornell University, made some determinations of the quantities of energy that are taken up per c.c. in wrought-iron cores of different degrees of lamination, at various degrees of magnetisation, and at different periodicities. The results are recorded in Table III.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 5 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

COMPOUND WINDING.

The judgment of the Court of Session in the action of KING, BROWN AND CO., *v.* THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION brings to a conclusion a lawsuit which can be compared only with that of the EDISON AND SWAN ELECTRIC LIGHT COMPANY *v.* HOLLAND AND OTHERS. The former is of greater importance to the general trade, affecting as it does every dynamo maker, large and small; while the latter was the "biggest" patent case on record. Had the principle of compound winding been discovered, and the method of carrying it out in practice been invented by one of the skilled staff of the Brush Corporation, one would naturally regret that the rudimentary and half-forgotten experiments of VARLEY, who, through lack of resources or want of zeal had allowed his machine to sink into oblivion, should have stood between the worker and the worker's due. But the patent in question was one item of the "Brush System" which the Corporation had acquired. Whether BRUSH ever really imagined in 1878 that the addition of the "teazer" or shunt winding to a series-wound dynamo would have the effect of enabling it to supply a variable current at constant volts, is an abstract question into which the Directors cannot be expected to inquire. Whether the "permanent magnetic field" which BRUSH mentions in his eighth claim was to obviate the difficulty that "in dynamo-electric machines as ordinarily constructed no magnetic field is maintained when the external circuit is open, except that due to residual magnetism;" or whether the construction of a dynamo which could "do a large quantity

Digitized by Google

of work" in electro-plating at one time, and "a small quantity" at another time, was a foreshadowing of distribution at constant potential, are also matters on which we cannot ask them to decide. The only real point is, the Brush Corporation have bought and paid for patent No. 2003 of 1878; can they justly claim royalties on all compound-wound dynamos? It is true that the teazer-wound dynamo gave a more useful characteristic than an ordinary series arc lighter; but, was this comparable for a moment with the compound-wound dynamo made by CROMPTON in the autumn of 1882, which ran glow lamps at constant volts for Mr. OCTAVIUS E. COOPE at Berechurch Hall?

In 1882 the patent was amended as to a few misprints and errors of spelling; and in February, 1886, the decks were cleared for action by extensive disclaimers. No definite movement was taken for some months, but, before the summer was over it was understood that the Brush Corporation intended to show fight. Several dynamo makers gathered round Messrs. CROMPTON AND Co., the acknowledged originators of constant-potential dynamos; and affidavits were obtained from eminent authorities who ranged themselves on either side, flatly contradicting each other, as is usual on such occasions. A good case was worked up; and each party, confident of victory, was at a loss to understand how their opponents could imagine they had a chance of success. But, one by one the supporters of the defendants withdrew, until the few firms who remained carefully computed the probable expenses of the case, and compared it with the amount they might expect to pay in royalties, allowing for extension of their output. The half-sovereigns per unit appeared to be the smaller burden, and the learned affidavits were pigeon-holed, the counsel were paid off, judgment in favour of the Corporation was agreed to in November, 1887, and licences were taken for compound winding. At a meeting of the Brush Corporation in March, 1888, the Chairman said, "We have every confidence in the strength of our position, and I am happy to say that that position has been recognised by all the leading makers in Great Britain. It is specially satisfactory to us that great firms like Messrs. CROMPTON and others, while they felt it their duty, of course, to oppose our claims, have behaved most honourably in this matter, and they took licences and agreed to pay royalties." In March, 1889, he said, "You know that we have a claim to have the controlling of the patents for compound winding of dynamos. That has been admitted by the English makers, and they are now paying us a royalty which amounts to a nice little income to us." These two statements looked very much as if the English makers had acknowledged that the claim was a just one. They did no such thing: they accepted the lesser evil. And here we must point out that the royalty was not a grievous burden; it fell practically on the purchaser; it was not in any way sufficient to divert orders for dynamos to Belvedere-road, nor do we suppose for a moment that such a diversion was intended.

Knowing the great expense of so important a lawsuit, considerable surprise was felt when Messrs. KING, BROWN, AND Co., of Edinburgh, in October, 1888, stated that the threat of the Brush Corporation with legal proceedings in respect of the manufacture of compound-wound dynamos had seriously affected their business, and accordingly applied for "the reduction" of the patent. We need not dwell upon the details of the case, as it is fresh in the memory of those of our readers who cared to study it. It is easy to criticise after the event; but it seems extraordinary that such great efforts should have been made to prove that VARLEY'S patent did not disclose sufficient information for enabling a compound-wound dynamo to be constructed. Whether VARLEY'S patent is sound is a matter of no importance, even to the inventor himself; as the patent, good or bad, has long since expired. Again, we were astonished at the amount of time spent over the commutator question—a mere side issue, and an accident, one of the few points that had not been expunged by the disclaimers from the comprehensive "omnibus" patent of BRUSH. The case was won fairly on the prior publication by VARLEY, and the issue was the fundamental one of compound winding. The Court of Appeal had a very clear idea of the case; the only two slips worth noticing are the designation of compound-winding as "a valuable electric appliance," and the suggestion that in a properly compounded machine "a nearly uniform current flows in the working field, notwithstanding variations in the quantity of work to be done." The work of CROMPTON, who was the first to place a self-regulating machine on the market, was not alluded to. CROMPTON not only brought out compound winding, but in getting up his case he brought out VARLEY, whose work had been completely forgotten. The Directors of the Brush Corporation have merely been doing their duty to their shareholders in endeavouring to make use of their property. The declared value of the patents of such Companies as this and of the Edison and Swan United form a serious portion of their load of capital; and in this respect the latter has to be congratulated on paying a respectable dividend on a capital which has never been reduced. Monopolies are a necessary consequence of the existence of patents. Ten shillings per unit is not much, but the extinction of one more tax will be welcome to the electrical trade.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

(Continued from page 279.)

§ 6. **Central Station at Rome.**†—In very fully describing this station in 1889, Prof. G. Forbes‡ called it the "finest example of an alternating-current central station;" and it well deserves this commendation. Since it was described by him it has been increased by the addition of two more large 600 horse-power engines and dynamos, and has now a complement of plant equivalent to a total output of 24,000 16 candle-power incandescence lamps. The electric lighting of Rome is carried out by the gas company, which has enlarged its operations and exists under the denomination of the Società Anglo-Romana per l'Illuminazione di Roma col Gas ed altri sistemi. The Directors of this Company were wise and far-seeing enough to recognise the necessity of dealing with the electric light either as an ally or as a rival, and in the spring of 1886 commenced operations for the supply from the gas works of the electric current by the Ganz alternating system. The gas works at Rome are in the Via dei Cerchi, near the Tiber, under the shadow of the Mount Palatine, and occupy a position in the region of old Rome, near the site of the ancient Circus Maximus; and in forming the foundations of portions of the heavy dynamo machinery some of the old arches of the Circus were exposed. The plan and elevation of the station are shown in Figs. 17 and 18, from which the general disposition of the machinery and buildings can be seen. The Central Station plant

consists of two similar small alternators of 80,000 watt-power, giving a maximum current of 40 amperes, at a pressure of 2,000 volts, which are coupled direct to engines of 125 horse-power, and of four large alternators of 320,000 watt-power, each giving a maximum current of 160 amperes at a pressure of 2,000 volts. The large dynamos are coupled direct to compound steam engines working up to 600 horse-power. The two smaller machines will be referred to as No. 1 and No. 2, and the four larger machines as No. 3, No. 4, No. 5, and No. 6, as shown in the plan. The four larger machines are not all similar in details. No. 3 and No. 4 are sister machines, and also No. 5 and No. 6; but the last two have many improvements not pre-

sent in the former two. Commencing our description with the first two, or smaller machines, these two dynamos were placed in position, and began to be used in the autumn of 1886. The general view of these machines is shown in Fig. 19. The engines are single-cylinder high-pressure engines by Gebrüder Sulzer, of Winterthur and Ludwigshafen. The speed is 250 revolutions per minute. These horizontal engines are built on a common bed-plate with the dynamo, and the revolving field-magnet of the dynamo forms the flywheel of the engine. The engines can be worked up to 150 horse-power. There are 20 coils in the fixed armature, and 20 poles in the stellate field-magnet, and in the armature all the coils are joined in series, each giving 100 volts, or 2,000 in all. In the field-magnets the coils are arranged in two series of 10 coils each, joined in parallel. The alternations are 5,000 per minute, or about 42 complete periods per second. These dynamos are auto-excited by a rectified alternating current and commutator, as above described, taking current from the secondary circuit of a field transformer, of which the primary coils are in connection with the armature of the alternator. The larger dynamos (placed in position and started in November, 1887), No. 3 and No. 4, are separately-excited alternators, coupled direct to 500 horse-power compound engines by Van den Kirchoffe, of Ghent. These last have elaborate expansion valve gear of Corliss type, and also centrifugal governors of the usual kind; they have also starting gear. The dynamo is placed between the high-pressure and low-pressure cylinder, so that the field-magnet is slung on the centre of the steel main shaft. The ring-shaped armature frame has massive projections or lugs on either side, supported by, and traversing in, guide bars like the bed of a lathe, and it can be traversed laterally by a screw, so as to move it off from and expose the field-magnet revolving in the interior. The interior diameter of the armature ring frame is about nine feet and a-half, and the over-all diameter of the stellate field-magnet rather more than nine feet. In the dynamos No. 3 and No. 4 the field-magnets have solid cast-iron cores and wrought-iron polar caps or projections; and these magnets, 40 in number, are placed round the periphery of an iron wheel keyed on the main shaft. The armature cores are built up of iron plates of thin sheet iron, with interposed paper, as described in a former section.

The two smaller dynamos, No. 1 and No. 2, also have armatures built in this way with divided iron cores, and with solid cast-iron field-magnet cores having wrought iron polar expansions. In the armature of dynamos No. 3 and No. 4 there are 40 coils, each generating 50 volts, and the whole of them are joined in series. In the field-magnets the 40 coils are joined up so that there are two series of 20 coils in each, and the two series are joined in parallel. The engines make 125 revolutions per minute, producing, therefore, an alternating current of 5,000 alternations per minute, or 42 complete periods per second. The armature coils will carry safely 200 amperes, but their normal load is about 160. The copper wire on the armature and magnet coils is six millimetres in diameter, or about one quarter of an inch.

The last two large machines, No. 5 and No. 6, are generally very similar to No. 3 and No. 4. They are driven direct by compound 500 horse-power engines by the Erster Brünner Maschinen Fabrik of Austria; and in this case also the dynamo field-magnet is slung as a flywheel in between the high-pressure and low-pressure cylinder. In order to give space for the stellate magnet and annular armature frame, a pit is formed between the high-pressure and low-pressure part of the engine. These last engines have governors of the type employed in the well-known Armington and Sims engine, in which the lead of the single eccentric is shifted and controlled by the outward movement of two massive weights contained in the interior of a pulley-shaped governor wheel. This governor is, for convenience, placed on the outside end of the main shaft of the engine. The general appearance of these last two 500 horse-power dynamos is shown in Fig. 20. These engines have been found to do their work remarkably well, and to govern steadily. The general principle of this centrifugal governor is that of causing a change of speed of the engine to alter the lead of the slide valve and so cut off the steam at different periods of the stroke. This is accomplished by carrying the valve eccentric not directly on the shaft, but on a sleeve which can be shifted in position on the shaft, so as to change the angle of lead of this eccentric from a position in which the eccentric axis is nearly parallel to the direction of the crank to one in which it is nearly at right angles to it. According to the degree of this angle of lead so will the steam be cut off almost at the beginning of the stroke, or at a point rather less than three-quarters of the stroke. The work done by the steam pressure can therefore be varied within wide limits. The shift of the sleeve carrying the eccentric is effected by a set of jointed rods, which are moved by a pair of heavy weights carried on the end of levers, which are carried round with the shaft either in the flywheel or in a special governor wheel. The outward movement of these weights, caused by the centrifugal action, is resisted by powerful springs in the governor wheel, and any change of speed operates directly to shift the lead of the valve. In these last dynamos, No. 5 and No. 6, the cores of the field-magnets, as well as the armature cores, are built up of laminated iron, as described in § 3. The bobbins of the field-magnets are formed of rectangular split zinc frames, about 15in. high and 20in. wide. They are wound over with the insulated wire, but more wire is placed at the bottom of the frame than at the top, and the finished bobbins have a slight taper from about 8in. to 6½in. in end width. The armature bobbins are shallow rectangular bobbins, wound on vulcanised fibre frames about 19in. long and 10in. wide and 2in. deep. Each bobbin has on it about 30 turns of highly insulated copper wire, about 6 mm. or ¼in. in diameter. The armature coils when slipped on to the laminated iron cores are kept in position by bobbin holders of bronze, which form a kind of skeleton frame clamped on the end. The more massive electro-magnet bobbins are secured by a similar bobbin holder, and by a bolt fastening it which traverses the whole width of the laminated core. The terminals of the field-magnet circuit are led to two insulated brass pulleys deeply grooved, which are secured on the shaft. Over these are slung flexible copper stranded cables, one end of which carries a pendant weight, and the other end of which is in connection with the excitor circuit. This affords an excellent, and yet perfectly flexible, contact surface, for the excitor current to enter and leave the alternator field-magnets. The mechanical performance of these latest machines is very excellent; the dynamos run very smoothly and quietly, and give no trouble by any heating or insulation defects.

To excite these four large dynamos, there are three excitors driven direct by Westinghouse engines of 50 horse-power each, made by Alley and Maclellan. The exciting dynamos are by Ganz and Co., and are four-pole continuous-current machines, which, at a speed of 375 revolutions per minute, give a current of 150 amperes and pressure of 180 volts.

Since 75 amperes is a sufficient exciting current for each of the large dynamos, one excitor can excite two of the large dynamos, and hence there is always one excitor in reserve. At full load the power absorbed in exciting is said to be 3½ per cent. of total absorbed power. The steam is provided from a plant of fourteen Babcock and Wilcox tubular boilers, each of 160 nominal horse-power. Coke is burnt in the furnaces. Four steam pumps, in addition to the usual injectors, supply water to the boilers. The total boiler horse-power is 2,240. The steam pressure is 120lbs.

There are, therefore, in this station three pairs of machines, each pair consisting of two similar independently driven dynamos, but all yielding a current at the same electromotive force, and having the same frequency of alternation.

(To be continued.)

---

300 Horse-power Transmitted 175 Kilometres.—From the *Elektrotechnischer Anzeiger* we learn that the Allgemeine Elektricitäts Gesellschaft have announced their willingness, in conjunction with the Oerlikon Company, to transmit 300 horse-power from the Neckar at Lauffen to the Frankfort Exhibition, a distance of 175 km. (about 109 miles), on condition that an ordinary overhead cable, 5 mm. in diameter, connecting the two places, is provided free of cost.

THE WORKING EFFICIENCY OF SECONDARY CELLS.*

By W. E. Ayrton, C. G. Lamb, E. W. Smith, and M. W. Woods, Associates.

(Continued from page 291.)

III.—*Automatic Current-Regulator.*

We think it possible that a neglect of the power that accumulators possess of drawing on a store of energy put into them in former chargings may have led experimenters to conclude that the normal efficiency of certain types of accumulators was greater than was really the case. To ascertain the *working efficiency* of the accumulators we were testing, it was clear that they would have to be charged and discharged alternately with a definite charging and a definite discharging current continuously for a much longer period than five days. And as this would be a very laborious operation if the current had to be kept constant day and night during this period by hand regulation, we proceeded to construct the automatic current-regulating device shown in Fig. 5.

A is a set of five accumulators under test, where B is a totally independent set of four used to provide the power for working the current-regulator. C is a platinoid strip of sufficiently large cross section and surface that no appreciable change of resistance can take place by the largest current—10 amperes—that flows through it in these experiments. D is a permanent magnet motor, the rotation of which in either direction turns the brass roller E F very slowly in one direction or the other, the pinion and toothed wheel of the motor, combined with the small grooved pulley on the toothed wheel shaft and the much larger grooved pulley on the roller, causing the angular motion of the roller to be about 1-500th of the angular velocity of the armature of the permanent magnet motor. The brass roller E F is electrically divided into two halves by the ebonite disc G, and little amalgamated discs at the ends of this roller turn with but little friction in mercury cups, H, I. Round each half of the roller are wound four bare platinoid wires of No. 26 gauge, and each about 4½ feet long. Their lower ends are soldered to the brass roller, and their upper ends to the brass bar, J K, small spiral springs (not shown in the figure) being introduced to keep the wires taut. The rod J K is held up by a cord which passes over two pulleys, and to the end of which is attached the weight L. An electric current, entering at H, follows the path H, E, J, K, F, I, the path being longer or shorter depending on the amount of the platinoid wires wound on the two halves of the brass roller. M is a solenoid, being, in fact, the coil of an A. and P. ammeter, on the axis of which a rod, P Q, was very delicately poised by its being supported by four very fine wires of No. 40 gauge, and each about one foot long. Two of the wires N, on a plane at right angles to the path, joined together where they were connected with the rod at Q, but spread out at the top, and similarly O consisted of two wires. Thus, while the rod P Q had great freedom of motion along its axis, it could not wobble sideways. This rod consisted of two pieces of brass at its ends, but the middle shaded portion was the well-annealed soft iron tubular core of the ammeter. A current passing round the coil M sucked in the core more or less against the pull of the antagonistic spiral spring P P'. This spring was made of platinoid wire of No. 26 gauge, wound round a ¾-inch mandril, and when pulled out in position it had about 30 turns to the foot, and was over four feet in length. One end of the spring was attached to the rod at P, while the other, P', was fastened to a fine thread, which could be wound up more or less round a small roller and the tension of the spring very delicately adjusted.

At first the elasticity of this spring was not perfectly constant, but after about one month's use the pull it exerted when stretched to a given length became wonderfully definite, and the core P Q could be adjusted, so that for a current of exactly 9 amperes flowing round the solenoid M the projection at P remained midway between the contacts R and S without touching either. But on the current flowing round the solenoid M becoming very slightly greater, or very slightly less, than 9 amperes, the platinised projection of the rod at P made contact with either the platinised piece R or S. The permanency that the spring eventually attained was so great that even when the apparatus had not been in use for two or three weeks one had only to close the circuits to start the regulator, and no fresh adjustment whatever of this spring was necessary to ensure that the current would be kept absolutely constant at 9 amperes. This spring has, however, now gone the way of most bare fine platinoid wire, of breaking up into pieces.

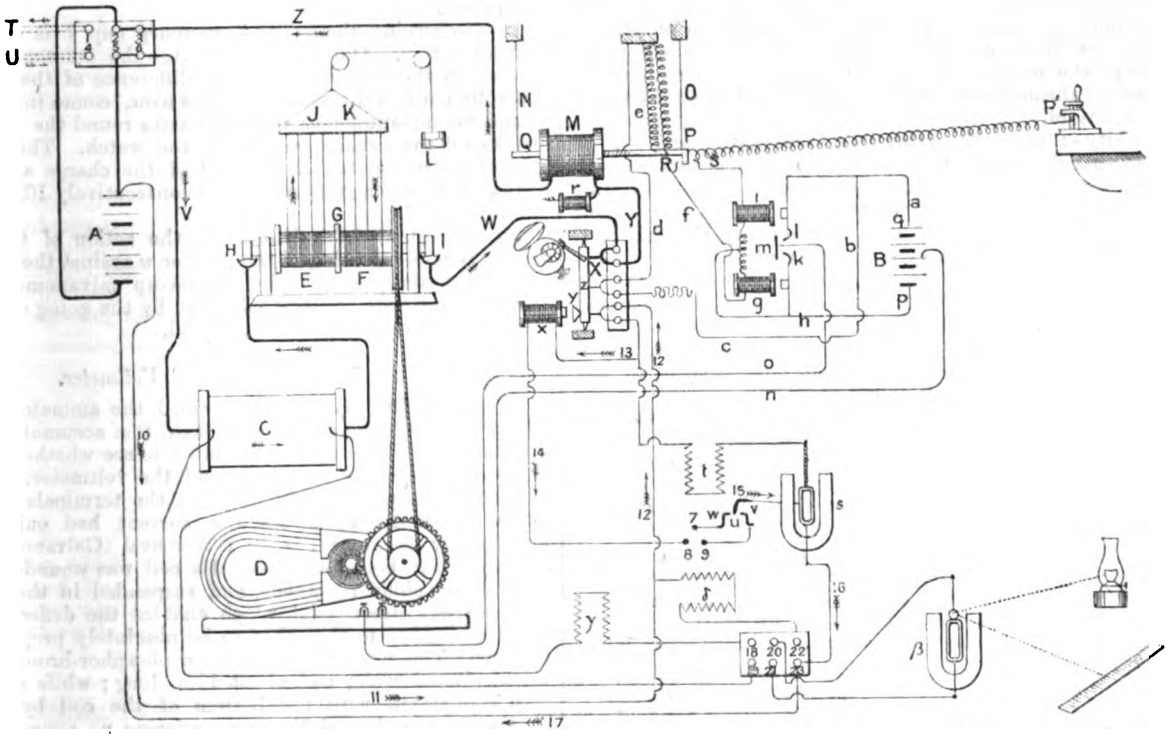

Fig 5.—Automatic Current Regulator and Automatic Interruptor for Breaking the Charging and Discharging Circuits.

When the cells A under test were being charged by means of a set of accumulators, not shown on the figure, but attached to the leads T and U, three copper bridge-pieces were put in to connect the mercury cups 4 to 5, 2 to 6, and 1 to 3 respectively; whereas when the test cells were being discharged two copper bridge-pieces connected the mercury cups 2 to 3 and 5 to 6. The current passed, of course, one way through the cells A in charging, and the other way in discharging; but in both cases a positive current flowed, as indicated by the arrows, through the thick lead V, the platinoid strip C, through H, E, J, K, F, I, through the thick lead W, the thick lead Y, the solenoid M, and the thick lead Z. As already explained, if the currents through this circuit exceeded in the very least 9 amperes, the core P Q was sucked into the solenoid M until P made contact with R; whereas if the current fell in the least below 9 amperes, P Q was pulled backed by the spring P P' until P made contact with S. In the former case a small auxiliary cur-

* Read at the Extraordinary General Meeting of the Institution of Electrical Engineers at Edinburgh, on July 16th, 1890.

Digitized by Google

rent from the accumulators B follows the course *a*, *b*, *c*, *d*, through the spirals *e*—several in number, so as to carry the current, but made of extremely fine wire, so as to oppose practically no resistance to the free motion of P Q—then from P to R, through *f*, the electro-magnet *g*, and through *h*, back to the other pole of the battery B. If, instead, P be in contact with S, then the current from the auxiliary accumulators B passes from P to S through the relay electro-magnet *i*, instead of through the relay electro-magnet *g*. In the former case the spring tongue *k* is attracted so as to make contact with M (M being in reality a mercury cup into which dipped a platinum point with which *k* was tipped), and in the latter case the spring tongue *l* is attracted so as to make contact with *m*. If *k* makes contact with *m*, a positive current commencing from the middle of the accumulators B follows the path *n*, the motor, through *o*, *m*, *k*, and back to the end of the accumulators *p*; whereas if *l* makes contact with *m*, a positive current follows the path *q*, *a*, *l*, *m*, *o*, the motor, through *n*, and back to the middle of the cells B.

Accordingly, then, as P makes contact with R or with S, a current is sent one way or the other through the armature of the permanent magnet D, and the roller E F is turned around one way or the other so as to unwind, or wind up, more of the wire and automatically alter the resistance in the circuit. Although the whole apparatus was home-made, and looked very rough, it was able to automatically keep the current constant to 1 part in 600 for days at a time.

As the charge was effected with 9 amperes and the discharge with 10, a shunt, *r*, exactly nine times the resistance of M, was connected across M during the discharge, and as the automatic regulator kept the current through M constant at 9 amperes, it kept the current through the circuit constant at 10 when the shunt *r* was attached to M.

The necessity of using the relay electro-magnets *g* and *i* arose from the fact that the only suitable permanent magnet motor which was at our disposal was a laboratory hand magneto Gramme machine which required a current of about 1 ampere to work it; and to obtain great sensibility the contacts between P and R or P and S had to be too slight to carry such a current.

It was very interesting to watch the regulator, since the armature of the motor was almost always in motion, now making half a turn one way, now one turn the other. It may be mentioned that one turn of the motor armature shortened or lengthened each of the platinoid wires by about $\frac{1}{6\frac{1}{2}}$ of an inch—that is, by less than the $\frac{1}{3000}$ of its whole length.

At first all sorts of plans were tried for keeping clean the surface of the mercury in the mercury cap *m*; but alcohol floated on the mercury failed because it dried up, water was electrolysed, oil was carbonised, and a long conducting point adhered to each of the platinum points *l* and *k*, and the auxiliary accumulators B were short-circuited. In despair we left the surface of the mercury completely exposed to the air, and were surprised to find that that answered perfectly: a thickish layer of mercury and mercurous oxide formed on the top, but the platinum wires easily forced their way through and always made good contact.

To avoid, however, all risk of accidents, cut-outs were introduced into various parts of the circuit: and to prevent the motor overwinding the platinoid resistance wires on the roller E F and breaking them, should the current in the main circuit accidentally become much too small, as well as to prevent the motor unwinding the wires too far off the roller should the current become much too large, safety keys (not show in the figure) were provided. If the rod J K were drawn down dangerously low, or allowed to go up too far, it touched one or other of the safety keys and broke the electrical circuits.

IV.—*Automatic Interruptor for Breaking the Charging and Discharging Circuits.*

As it was extremely important that both the charging and discharging circuits should be broken at the exact moment when the potential difference in its rapid variation passed through certain specific values, and as in a long course of experiments, lasting for several months, it was quite possible that occasionally no one of the observers would be present at the exact moment, we arranged an interruptor to break the circuit automatically when the potential difference in charging reached 2·4 volts per cell, or 1·6 volts per cell in discharging. The automatic interruptor was arranged thus: *s* is a D'Arsonval galvanometer, the coil of which, wound with platinoid wire of 154 ohms resistance, is joined in series with a resistance box, *t*, as a shunt to the accumulators A under test. Electric connection was made with the bottom of the coil by means of a fine spiral spring too thin to introduce any controlling moment, while above the coil was suspended by a phosphor-bronze strip 1-1,000th inch thick, 12-1,000ths broad, and 1¾in. long. This strip had seven twists put into it by means of a head moving in a tight collar, the coil being prevented from turning by a pointer, *u*, attached to the framework of the coil coming into contact with the stop *v*. The thin phosphor-bronze strip being very thin, it had very little torsional rigidity, and being set up as described, this instrument acted as a "set-up voltmeter"—a type of instrument proposed some years ago by Prof. Perry and one of the authors of the paper for measuring with great accuracy a very small change in a potential difference. With a definite adjustment of the resistance in the box *t*, the platinum-tipped pointer *u* remains in contact with the stop *v* for all potential differences between the terminals of the accumulators A less than 2·4 volts per cell. When the potential difference reaches this value the pointer at once leaves the stop *v*, moves over through an appreciable distance, and makes contact with the platinum-tipped stop *w*. With another definite adjustment of the resistance in the box *t*, the pointer *u* remains in contact with *w* for all potential differences between the terminals of the accumulators A greater than 1·6 volts per cell, but the moment this value is reached the pointer moves away from *w* and makes contact with the platinum-tipped contact-stop *v*.

When charging, a copper bridge-piece connects the mercury cups 7 and 8, and when, on the potential difference at the terminals of the accumulators A reaching 2·4 volts per cell, the pointer *u* passes over and makes contact with *w*, an instantaneous small current is sent by the accumulators A through the electro-magnet *x*, which attracting the armature *y* downwards, tilts the spindle *z*, and thereby lifts X and the other two contact-forks out of the three sets of mercury cups, thus breaking *all* the circuits. The tilting of the spindle *z* also brings a camel's-hair brush into contact with the balance of a watch, and stops it at the moment the charging is completed.*

In discharging the cells A mercury cup 7 is connected to 9 instead of to 8. During the discharge the pointer *u* rests against *w*, and on the terminal potential difference of the cells falling to 1·6 volts per cell the pointer moves over, comes into contact with *v*, and an instantaneous current passes round the electro-magnet, breaks all the circuits, and stops the watch. The course of this instantaneous current at the end of the charge and discharge is indicated by the arrows numbered consecutively 10, 11, 12, 13, 14, 15, 16, and 17.

To prevent any sluggishness in the action of this interruptor from a possible sticking of the pointer *u* against the contact-stops *v* or *w*, the pedestal supporting the set-up galvanometer *s* was kept in a constant state of slight vibration by the going of an American clock that was placed on this pedestal.

V.—*Ammeter and Voltmeter.*

There remain only to be described the ammeter, by means of which the current passing through the accumulators could be measured from time to time, in order to see whether the automatic regulator was doing its duty; and the voltmeter, for frequently measuring the potential difference at the terminals of the accumulators, A, under test. As the current had only to be very occasionally measured, one D'Arsonval Galvanometer, *β*, was employed for both purposes. Its coil was wound with platinoid wire of 52 ohms resistance, and suspended in the way that has been already described,† which enables the deflection from one end of the scale to the other to be absolutely proportional to the current. The top suspension was a phosphor-bronze strip $\frac{1}{1000}$in. thick, $\frac{1}{16\frac{1}{2}}$in. wide, and about 1¾in. long; while electric contact was maintained with the bottom of the coil by means of an extremely fine A. and P. spring, offering no appreciable torsional rigidity. The permanent magnets employed belonged to an old magneto machine, and into the cylindrical space between their poles, in which the Siemens armature formerly turned, was put a coil made of the right shape to suit the curved ends of the magnets without it being necessary to employ any soft iron pole-pieces. Experiment showed that the deflection right across a scale 2ft. 9in. long. the zero for no current being at one extreme end, was rigorously proportional to the current—a result which, as has been already pointed out, is very far from being obtained with D'Arsonval galvanometers as usually constructed.

When it was desired to measure the current passing through the accumulators, A, a rocking switch was turned so as to connect mercury cup 18 to 20, and 19 to 21; whereas when it was the potential difference at the terminals of the accumulators that was to be measured, the rocking switch was turned so as to connect mercury cup 20 to 23, and 21 to 22. In the former case, with a resistance of 264 ohms on the resistance box *γ*, a current of 10 amperes passing through the cells and platinoid strip C produced a deflection of 500 scale divisions, or 50 divisions per ampere; while, with a resistance of 71,570 ohms in the resistance box *ε*, a potential difference of 10 volts at the terminals of the five accumulators A under test produced the same deflection; so that 50 divisions corresponded then with 1 volt.

* As it was undesirable to risk an expensive watch, we purchased one of the watches that could be then obtained in St. Paul's Churchyard for 3s. 5½d. This watch was very substantial, had a very strong hair-spring which could not be easily damaged, and was an excellent time-keeper—far superior to many watches of a far more expensive character.

† See Paper on "Galvanometers," *Phil. Mag.*, July, 1890.

VI.—*Results obtained with Automatic Apparatus.*

Many preliminary experiments having been made with the automatic apparatus, we succeeded in making it work quite satisfactorily by the beginning of May, 1889, and it was adjusted to charge five accumulators, A (Fig. 5), with a steady current of 9 amperes until the potential difference reached 2·4 volts per cell, and to discharge them with a steady current of 10 amperes until the potential difference fell to 1·6 volts per cell. After 12 days and nights had been spent in continuous charging and discharging, the cells reached a normal state, the time rise of potential difference in charging and the time fall in discharging being at length repeated over and over again, so that when the time curves were drawn for the successive charges they exactly coincided, and so for the discharge curves. The areas of these curves—reckoned, of course, from the zero of potential difference, which is much below the figure as here show—may thus be said to give the "working watt-hours" for charge and for discharge when the charge and discharge are effected between limits of 1·6 and 2·4 volts per cell. Fig. 6

Time in Hours from Beginning of Discharge

Fig. 6.

shows the discharge curves obtained on May 16th, 17th, 18th, and 19th, the points for each of the discharges being indicated by points differently marked as stated on the figure; and Fig. 7 shows the intermediate charge curves obtained on May 17th, 18th, and 19th. Integrating these curves, we find—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
115	221·8	117	256·2	98·3	86·5

Soon after this very concordant set of results was obtained, the time of charging, which had remained steadily at 13 hours from the commencement of May, began to increase to 15½ hours, while the time of discharge only increased half an hour—that is, to about 12 hours. At first we thought that we had been trying to charge the

cells too much, so we stopped the charging when the potential difference per cell rose to 2·35 volts; but the time of charging still continued to increase, until at last it rose to 24 hours, the time of discharge still remaining about 12 hours. On again reducing the potential difference limit on charging, the potential difference per cell now refusing to rise to 2·35 volts, both the times of charging and discharging became very irregular, and at length the time of charging suddenly fell to 10 hours and the time of discharging to 6. On carefully examining the plates, they were found to have badly scaled, and to have suddenly become partially short-circuited; they were therefore carefully scraped, and the mud allowed to settle at the bottom, where, in consequence of the special construction of the 1888 cell, it could remain without short-circuiting the plates. Only a few plugs fell out in this operation. This sediment was afterwards weighed and analysed, showing a composition that will be referred to in Section VIII., on the Chemical Action.

We now concluded that we had been running the cells too low, and we therefore decided to stop the discharge when the potential difference per cell fell to 1·8 volts, retaining the higher limit of 2·4 volts per cell to limit the charge. It is interesting to notice that Dr. Louis Duncan and Mr. H. Wiegand, in their paper on "The Inherent Defects of Lead Batteries," read before the American Institute of Electrical Engineers, and which we saw for the first time at the end of June, 1889, reprinted in the *Electrical World*, come to exactly the same conclusion—that the discharge should be terminated at 1·8 volts per cell, otherwise there is a formation of white lead sulphate, and a rapid depreciation of the cell. From what we have since seen, we think that the discharge should be stopped even still sooner—when the potential difference per cell has reached 1·9, or 1·85 volts at the lowest.

(To be continued.)

ELECTROLYTIC SEPARATION OF METAL AT THE FREE SURFACE OF A SALT IN SOLUTION.*

BY DR. J. GUBKIN.

1. When a current of electricity passes from the solution of a salt into a vapour or a gas, electrolytic separation of the metal must occur at the surface of the liquid. At the suggestion of Herr Warburg I have made one or two experiments to determine how the separation of metal takes place in such a case.

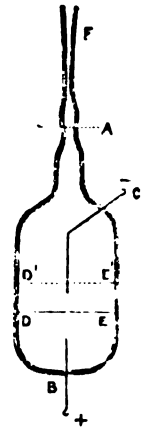

Fig. 1.

2. It is best to render the space above the liquid free of air. For this purpose the apparatus shown in Fig. 1 was used. It consisted of a glass vessel in which two platinum wires, B and C, were sealed—B being plated electrolytically with the metal to be separated from the solution. The latter was introduced to the level D′ E′ and boiled for about ten minutes until its surface had sunk 4 or 5 mm. below the point of the wire C. While the vapour was still escaping the vessel was closed at F with shellac; and, after cooling, the neck was melted off at A. The apparatus then appeared sufficiently free from air.

In order to reduce the vapour pressure, the lower part of the vessel was placed in ice, the upper part being freed by warming from any liquid that still clung to it.

A battery of 1,000 Planté accumulators was then connected—the positive pole with B, the negative with C; upon which there appeared at C the well-known negative glow.

3. When the vessel contained nitrate of silver, the following was observed:—Soon after putting on the current a small round disc of bright silver was formed just underneath C. As the disc increased in diameter it darkened at the centre, and there was formed upon it a series of light and dark concentric rings, which were sometimes coloured—some of these showing radial markings which gave them the appearance of divided circles. The disc did not sink, provided the apparatus was kept from shaking.

4. With a solution of zinc sulphate there was no separation of metal to be seen; but on looking at the surface D E from below,

* *Wied. Ann.*, 32, p. 114, translated by Mr. A. P. Chattock, and communicated by Dr. Lodge, Secretary of the Electrolysis Committee of the British Association.

Digitized by Google

white flocculent masses of zinc oxide were visible, slowly sinking through the liquid. The zinc on separation by the current was thus immediately oxidised.

5. For experiments with a solution of platinum chloride the apparatus in Fig. 2 was used; in this the chlorine was collected over B.

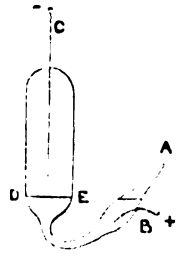

FIG. 2.

A short time after closing the circuit there was visible just opposite C a small lump of dead black platinum. On stopping the current this floated to the side of the vessel, but returned to its original position just opposite C, when the current was again started, thus preventing the formation of a fresh lump. Very probably this phenomenon was due to electric forces.

6. These experiments may also be carried out in air by means of an induction coil. The liquid is contained in a funnel, as in Fig. 3,

FIG. 3.

and the discharge at "break" furnishes the necessary current, the spark gaps between the solution and the cathode being arranged to prevent a discharge at "make" from taking place. In this manner experiments with silver, zinc, and copper solutions were carried out, with results substantially the same as those described above; except that here the space flowed through by the current, and, consequently the diameter of the silver disc, was smaller than before. The concentric rings were, however, clearly visible.

A PROOF OF MAXWELL'S THEORY OF RESIDUAL CHARGES.*

BY H. MURAOKA.

According to Maxwell's theory no residual charge can appear in a perfectly homogeneous dielectric, whereas parallel layers of various dielectrics, each homogeneous in themselves, will give a residual charge, provided none of them is a perfect insulator. The first part of the theory has been already established by the researches of Rowland and Nichols, Hertz, Arons, and Dieterici. The author of this paper succeeded in proving the truth of the second part by Dieterici's method. He superposed layers of two of the dielectrics, paraffin oil, petroleum, castor oil, oil of turpentine, xylol, paraffin and air, and with some exceptions found considerable residual charges. The exceptions occurred when two good insulators or two miscible fluids were chosen. When one dielectric is soluble in the other, as for instance paraffin in xylol, the residual charge disappears. Maxwell's view would lead one to expect a residual charge where the dielectric consists of microscopically minute particles of different substances. This, therefore, cannot be the nature of the solution.

* Wiedemann's *Annalen*, Bd. 50, Heft 6, 1890.

THE ELECTRIC LIGHTING OF BRIGHTON.

We were able to give in our issue of the 11th inst. the successful tenders for the electric lighting of the Borough of Brighton. Below will be found the complete list of tenders sent in:—

For Section A. (Buildings.)

Mr. G. G. Garbutt	£5,413	9	5
Messrs. J. Longley and Company	4,236	0	0
Mr. J. T. Chappell (accepted)	3,989	0	0

For Section B. (Boilers, &c.)

The Brush Electrical Engineering Company (Limited)	£3,366	0	0
Crompton and Company (Limited)	3,150	0	0
Messrs. Fraser and Fraser	2,767	0	0
Messrs. Wm. and John Yates (accepted)	2,734	0	0
Messrs. Sharp and Kent	2,715	0	0
Messrs. James Johnston and Company	2,545	0	0
Messrs. Alfred Anderton and Sons	2,530	0	0
Messrs. Nicholson and Jennings	2,378	4	0

For Section C. (Dynamos, &c.)

Latimer, Clark, Muirhead, and Co.	£11,946	0	0
The Electrical Construction Corporation (Limited)	11,595	0	0
Siemens Brothers and Company (Limited)	11,265	0	0
The Brush Electrical Engineering Company (Limited)	11,258	0	0
Messrs. Charlesworth, Hall and Co.	11,188	0	0
Siemens Brothers and Co. (Limited)	11,040	0	0
Messrs. Johnson and Phillips	10,496	10	0
The Electrical Construction Corporation (Limited)	10,022	0	0
Siemens Brothers and Co. (Limited)	9,950	0	0
The Gulcher (New) Electric Light and Power Co. (Limited)	9,800	0	0
Siemens Brothers and Co. (Limited)	9,725	0	0
The Electrical Engineering Corporation (Limited)	9,586	0	0
Crompton and Co. (Limited)	9,455	0	0
The India Rubber, Gutta Percha and Telegraph Works Co.(Ld.)	9.164	0	0
Messrs. Sharp and Kent (less various extras) (accepted)	7,997	10	0
Messrs. Nicholson and Jennings	7,512	4	0
Messrs. Sharp and Kent	6,975	0	0

For Section D. (Batteries.)

Siemens Bros. and Company (Limited)	£8,000	0	0
Crompton-Howell, E. L. Company (Limited)	7,440	0	0
Crompton and Company (Limited)	7,336	0	0
Mr. J. A. Timmis	6,262	12	0
Siemens Bros. and Company (Limited)	5,825	0	0
Messrs. Sharp and Kent	5,530	0	0
The Brush Electrical Engineering Company (Limited)	5,504	3	0
The Electrical Construction Corporation (Limited) (accepted)	5,242	0	0
Messrs. Johnson and Phillips	5,000	0	0

THE BIRMINGHAM BRISTOL-ROAD ELECTRIC TRAMWAYS.

Major-General Hutchinson, Board of Trade Inspector of Tramways, last week made a formal and official inspection of the new electric tramways which the Birmingham and Central Tramways Company have laid along the Bristol-road from Navigation-street, in the city of Birmingham, to Bournbrook on its outskirts. Major-General Hutchinson, accompanied by Major Cardew, Mr. Joseph Smith (chairman), Mr. W. J. Carruthers-Wain (managing director of the Central Company), Mr. H. Lea (electrical adviser to the City Council), Mr. J. Kincaid and Mr. E. Pritchard (engineers), Mr. A. Dickenson (consulting mechanical engineer), Mr. T. Parker (representing the Electrical Construction Corporation), together with some twenty other passengers, made a trip of about three miles to Bournbrook. While running at full speed, the car was stopped suddenly with the view of testing the brake. The car pulled up in its own length; but this did not satisfy the inspector. On the outward journey the bogie on which the motor was fixed was the foremost, but on the return journey the inspector ordered the position to be reversed and the car to be driven forward. The passengers were also requested to sit as far as possible at the rear of the car. This was done in order that the efficiency of the motor might be tested under the most difficult conditions. On the decline between Wellington-road and Belgrave-road the car was again pulled up to test the brake, with the capacity of which the inspector was still not satisfied. At the curve into Navigation-street the speed was increased, and the car passed safely over at a great pace. The brake was again applied, and the car pulled up within a length. After three further trials of the brake Major-General Hutchinson suggested two or three alterations in the appliance with a view to increase its efficiency, and the Chairman of the Company promised that these should be carried out. The inspection—which in every respect, save the brake, had passed off in a completely satisfactory manner—then terminated.

The old horse-line was of 4ft. 8½in. gauge, and had fallen into a very bad state. The line has now been reconstructed throughout on the same gauge and in the same manner as the rest of the Central Company's line in and around Birmingham. The rails are of steel, in girder sections, 6in. deep with a 7in. flange, and weigh 92lb. to the yard. They are secured in the most solid manner, with steel fish-plates 2ft. long by 6½in. bolts, and the points are of Siemens open-hearth steel. The rails are set in a bed of Portland cement concrete, 6in. thick, and the area between the lines and for a space of 2ft. 6in. outside the metals paved with wood blocks with an edge of serrated granite setts to bind with the macadam of the rest of the roadway.

The depôt for the section is at the Bournbrook terminus, standing about 80 yards away from the main line, and covers an area of three-quarters of an acre. The buildings comprise traffic office, engineer's office, men's room, stores, switch room, accumulator room, lead-melting store, machine and fitting shops, engine and boiler houses, coal store, and large car sheds and charging station The charging station, 75ft. long and 63ft. wide, where the spent batteries are removed and replaced by freshly-charged cells, forms the front of the depôt. Lines run through it into the car shed, which is of uniform width with the charging station and 100ft. long, and underneath the lines are pits to facilitate examination of the gear of the cars. Four hydraulic elevators are provided for supplying and removing the cells to and from the cars, and each has eight shelves capable of storing sufficient cells for 16 cars. In addition to this there are shelves in the accumulator room which will carry sufficient cells for two further cars. The charging of these can be carried on simultaneously with the batteries on the elevator cages. The elevator cages are open, so that the cells are always under control and examination. A chamber underneath the elevators enables them to fall below the road level, and allows for examination of the hydraulic machinery.

The engines and boilers and machinery to generate the electric force are all laid in duplicate, each engine is guaranteed to deliver 100 horse-power from the fly-wheel. The two boilers are of steel, of the "Economic" safety multitubular type, 12ft. 6in. long and 7ft. 6in. diameter, and the flues, 28in. in diameter, are fitted with two Galloway tubes and with Paxman's expansion joint and other best-known appliances for heat economising and smoke consumption. Provision is made for feeding the boilers either by injectors or by steam pumps either direct or through a "Green's economiser." The boilers are built to work at 120lb. on the square inch. During the excavations at the depot the engineers came upon a fairly constant water supply, which, together with the rain water, will be carried first into an underground tank in which the roof and surface drainage runs, and subsequently pumped to a large tank on the top of a tower 30ft high. It will then pass through a "Jewell" filter, and be used for feeding the boilers and washing the cars. Sand is used as the filtering material, together with a coagulated form of soda ash. A pressure of 3lb. per square inch will pass the water through the filter. The engines are of the "Receiver" type, non-condensing, with high and low pressure cylinders side by side, the former 12½in. diameter, and the latter 20in., and the length of stroke 24in. Paxman's automatic expansion gear is fitted. The fly-wheels are 8ft. 6in. diameter, and 17in. wide, and will make about 100 revolutions per minute. The leather link belting to drive the dynamos is carried in a belt-race lined with white glazed bricks, and this and the engines are enclosed by brass railings in cast-iron standards.

The two dynamos are in the engine room. They are of the "Elwell-Parker continuous-current" type, shunt-wound, with a capacity of 100 volts, 500 amperes, at an approximate speed of 540 revolutions per minute. Each dynamo will thus supply accumulator cells for twelve cars, in addition to the lighting of the depot, and power for the 9 horse-power motor in the machine-tool shop. Slides are provided for tightening the belts. The brushes, which are so arranged as to bear lightly on the accumulator, are carried in movable rockers. Two spare armatures to fit either dynamo are provided. Resistances are arranged for maintaining constant volts at the dynamos. The batteries are of Elwell-Parker make, with ten negatives and nine positives, 8½in. by 6½in., with vulcanite separators. The cells, which are in vulcanite cases, are firmly secured in teak trays. 96 of these cells are required for each car, giving a total force of about 192 volts, and yielding a current of about 35 amperes. From the construction of the cage-elevators any number of cells can be charged at one time, and the operation of connection is automatic. Portable voltmeters and hydrometers are used during charging. Strips of copper run along the guides of the lifts, the current is taken off by spring contacts. These strips are connected through fuses to a switchboard. There are five of these boards, each having ammeters, fuses, resistances, and switches for the eight shelves of the hydraulic lift. The cables from the five boards are led along the tie rods of the roof to a main switchboard provided with Cardew voltmeters, ammeters of a capacity of 600 amperes, and main fuses and switches. The whole of the buildings are lighted by 16 candle-power incandescent lamps, with two 200 candle-power lamps over the entrance to the charging station.

The hydraulic pumps provide a supply of water at a pressure of 700lb. to the square inch by accumulators to the lifts. The car sheds, charging sheds, boiler and engine house are paved with cement concrete, and the mechanics' shop and battery room with wood block flooring. The boiler chimney is 110ft. high, with a diameter of 4ft. at the cap, and is lined with 4½in. fire-brick. A lightning conductor runs down the shaft into the underground tank already mentioned.

The electrical and mechanical fittings have been supplied by the Electric Construction Corporation, of Wolverhampton (late Elwell-Parker's), and are on the "Julien" principle. The cars are 26ft. 6in. long, with platforms at either end, and 6ft. 3in. wide, and have a carrying capacity for 24 inside and 26 outside passengers. The body of the car is carried on two bogie trucks of T iron, strengthened by King trusses, and about 15ft. between centres. They resemble the cable cars of the same Company. The outside seats are reversible garden chairs, and inside are of the usual longitudinal kind, with a centre passage. The woodwork below the plate-glass windows is polished teak, in panels which slide vertically, so as to give access to the trays and cells underneath the seats. There are six trays on each side of the car, and each tray holds eight cells, making 96 in all, and the teak trays are carried in three runners on the car floor. When the trays are pushed into the cars they are secured and automatically connected-up by V-shaped copper contact blocks, and the conductors from cells (in four groups of 24 each) brought up to switch used by the driver. By this arrangement the four groups of cells may be connected with the motor in six different ways, and the necessity of resistance coils in the circuit is obviated and uniformity of discharge is secured.

The first position of the switch leaves all the groups disconnected; the second puts them in parallel, but not in circuit with the motor; the third puts them on to the motor; the fourth puts the groups half in series and half in parallel; the fifth cuts out one group, leaving three in series; and the sixth position couples all in series. The object of the second position is to allow an equilibrium to be made by the batteries in case one group has run down more than the others. The other positions obviously give one-quarter, one-half, three-quarters, or the full volts. The arrangement is covered by one of the Julien patents. It will be noted that no resistances are used on the car.

The motors are of the Elwell-Parker type, double limb, series wound, and run with 140 revolutions; but a velocity of 700 revolutions is required to maintain a speed of eight miles an hour. One motor is supplied to each car and carried on one of the bogie trucks by means of an aluminium brass frame, three points of which are rigidly fixed on one axle of the bogie, and the fourth rests on the second axle through a strong helical spring that makes it independent of any change of load or oscillation of the car. A helical pinion on the motor shaft gears with two intermediate wheels on two countershafts, which drive the axles of the bogie by other helical-geared wheels, the whole ratio being about 6¼ to 1. The driver's switch is placed underneath the steps of the platform in a teak matchboard casing, and quite out of the way of the passengers. The inside seats of the car are hinged so as to afford access to the accumulators, and the portion of the floor over the motor is also movable. The cars will be lighted by a 16 candle power incandescent lamp at each end, and the brake provided is of great power, gripping all the wheels at once.

The Public Works Committee has not given its consent to the running of electric cars, but the Company has been informed that no objection need be anticipated. All the cars have been delivered, and as soon as the necessary permission is obtained the service will be commenced.

The permanent way outside the city and also the buildings at the depôt were designed by Messrs. E. Pritchard and Joseph Kincaid, engineers to the Company; and the whole of the works have been executed under the superintendence of Mr. A. W. Pritchard for the engineers.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 11, 1890.

Steam Supply.—The New York Steam Heating Company, which has been responsible for much damage in the lower part of the city, and which has seriously interfered with the electric subways in the locality, seems at last to have overtaxed public patience. It has been ordered to cut off steam from its mains

Digitized by Google

throughout the larger part of Lower Broadway; and legal steps will be taken to see that the order is obeyed. The pipes in their present situations are condemned as a public nuisance.

Physiological Effects of Current.—Dr. Edward Tatum, whose experiments on the physiological cause of death by electricity have attracted some attention, is likely to continue further investigations on the subject. His work down to the present time has done much to clear up the subject he has taken in hand, and is especially interesting as it calls special attention to the differences which exist between continuous and alternating currents in their effects upon a living organism. He has made it very evident that the continuous current does not kill through any action upon the nervous system, but rather through direct effect upon the substance of the heart. The alternating current, on the other hand, does its work in large measure through action upon the nerves and inhibitory mechanism of the heart, thus producing more fatal results in proportion to its actual current strength.

Traction Experiments.—A vigorous effort has been made to depreciate electrical traction by the publication of some experiments tried on the New York elevated roads more than a year ago. The Paper shows a lamentable degree of ignorance on the part of the author of what has been done even in electric street-car work. The experiments showed an efficiency from engine to car wheel of only 15 per cent., whereas it is notorious that 50 per cent. can be reached in street-car practice on a line of similar length. The cause of this extraordinary result may be found purely in the fact that the engine-furnishing power was of about 500 horse-power, while the actual effort required to draw the train at the speeds employed was less than 30 horse-power. To draw any conclusions as to the economy of electrical traction from an efficiency computed with such data shows dense ignorance of the ordinary principles of mechanics. The speed of the train with which these experiments were made was so slow, too, that the motors must have been working at an efficiency far below the normal, although the details are not given in the Paper read by Mr. Moss. The constant loss from friction of engine, dynamos, and open-circuit losses on this line amount to more than 40 horse-power, which renders the deductions made from the experiments absurd, if anything more were necessary than the facts regarding the size of engine which I have just given.

The Duncan Motor.—Some experiments recently tried with a motor invented by Dr. Louis Duncan, of Johns Hopkins University, have given results so remarkable as to attract considerable attention. The motor is a multipolar machine of 15 horse-power nominal, and an output of 10 horse-power was obtained from it at an electrical efficiency of 92 per cent., and a speed of 90 revolutions per minute; this in spite of the fact that the armature was of cast iron. This very remarkable result is obtained by employing a large number of poles, and a commutator with rather complicated cross connections. Unless further experience should show results remarkably below those accepted by the experimental machine, it would seem that we have here a solution of the difficulty heretofore met in electric traction—that is to say, the necessity of high armature speeds and geared motors. Dr. Duncan is certainly to be congratulated on his remarkable success with the new machine.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *July* 12, 1890.

Sweden's telegraphic correspondence for last year amounted to 1,768,892 messages, of which 60,140 messages were for service and meteorological telegrams, and for these no fees were paid. There were also transmitted about a million "repetition" telegrams. The chargeable telegrams consisted of 939,624 inland and 769,128 foreign, and 182,569 messages passed through the country, mostly between Russia on the one and England on the other side. Of the telegrams 13,990 were State messages, and 18,917 express telegrams. Compared with the chargeable telegrams of 1888, there is an increase of about 25 per cent. Of these the home traffic represents an increase of 52·2 per cent. The receipts from the telegrams amount to 1,393,732kr., or 13,094kr. less than 1888, a decrease equal to 0·9 per cent. The decrease is, of course, caused by the reduction in the charge for inland telegrams. Home telegrams have yielded about 0·73 öre (about 10d.) per message, and the international telegrams 0·92 öre (a trifle above 1s.) per message. The Swedish share of direct foreign telegrams was, however, 1kr. 14 öre (about 1s. 3d.), and on the transit telegrams only 0·24kr. (or about 3d.). Last year the average pay for home telegrams was 1kr. 13 öre (1s. 3d.), but the charge was reduced to half at the beginning of 1889.

Although, of course, large quanti ties of electric fittings are imported into Sweden, yet the manufacture within the country is continuously extending. As a recent example, may be mentioned the erection in Gothenburg of a manufactory for incandescent lamps. At these works will be adopted a new proces for repairing or restoring incandescent lamps, which is said to have given very good results.

The installation for electric street lighting of Sundsvall, Sweden, has been secured by the firm of Eriksens, Mekaniska, Balog, Stockholm, as agents for Siemens and Halske, Berlin. The contract comprises three dynamos, accumulator, and 50 arc lamps. The cost is about 82,000kr., and the works will be completed by Christmas.

The electric lighting of the Royal Castle at Stockholm has been gradually extended, both in the interior and outside the huge building. Nine ampere arc lamps will be placed outside the southern and western entrance gates of the Castle.

Some of the apartments of the Castle of Fredensborg have also been fitted with electric light lately, which is now making steady progress in many parts of Scandinavia, where there has hitherto been a considerable opposition against it, especially in Denmark.

The Stockholm Bell Telephone Company held its annual meeting the other day, and although it can of course not vie with the Stockholm General Telephone Company, it shows fair progress. The subscribers numbered at the end of last year 1,751, of which 1,324 were the Company's own subscribers, and 327 subscribers in other societies. The gross profits amounted to 140,446kr., working expenses were 85,815kr., and interest 6,240kr. The net profits were applied to various writings off, and no dividend was declared.

The State telegraphs in Norway show a considerable increase in receipts, and the reduction in charge for telegrams, which was adopted some three years ago, has brought about a material increase in the takings. In the financial year 1887-88, previous to the change, the takings amounted to 868,000kr., but rose in the next financial year, after the introduction of the reduced charge, to 1,013,000kr. In the last financial year there was a further rise, and for the pending year they have been estimated at 1,120,800kr. During the pending year a sum of 167,800kr. will be applied to new State telegraph and telephone installations. Continuation of the Vodsö-Toneneto telegraph will require 60,000kr.; a third wire on the Vaterfjord-Lodingen line 23,500kr.; line from Ulne to Odde 26,000kr.; line from Flekkefjoord to Hiterö 10,000kr.; line from Ölen to Sand, 25,000kr.; telephone to Grindaheim in Volders, and extension of the Töusaasen-Fageruös Telephone 15,300kr., &c. Altogether, a number of out-of-the-way places are gradually being brought into telephonic communication with the world at large, either by State telephones or private enterprise. During the financial year 1888-89 the profits on the Norwegian State telegraphs have been 163,000kr. more, and expenses 6,000kr. less than calculated, a state of affairs which can but be called satisfactory.

Delegates from the Aalborg, Aarlens, Fredericia, Grenaa, Habro, Holstebro, Sljörring, Randers, Ringkjöbing, Silkeborg, Skive, Veile, and Viborg telephone companies in Jutland held a meeting last week. A committee was appointed for the purpose of framing rules for a joint management of all the telephone companies in Jutland.

CORRESPONDENCE.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I venture to trespass on your valuable space in reference to a matter which is engaging a considerable amount of attention among electrical contractors at the present time, viz., fire office rules.

Formerly most contractors carried out their work as nearly as possible in accordance with the Phœnix rules, but now nearly every fire office has a special set of rules for electric lighting on its own account. This was, of course, to be expected, as competition among insurance offices is as keen as in any other business.

What is the electrical contractor to do? In an important installation the building and contents are often insured in three

Digitized by Google

or four leading offices, all of whom ask if the work has been carried out in accordance with their particular rules; and how can this possibly be done when the rules vary in important respects?

It seems to me that the sole remedy is for electrical contractors to work carefully in accordance with the rules laid down by the Institution of Electrical Engineers. If these rules are considered insufficient in any particular respects contractors will soon hear of it, and where there is any consensus of opinion a report should be made to the Institution, and a periodical revision of the rules undertaken by a committee.

This, I believe, would do away with the present hopeless condition of affairs, when a surveyor from one leading office expresses great satisfaction with work one day; and the next day a surveyor from another equally important office swoops down and harasses the contractor by demanding alterations, which can best be described by F A D in capitals.—Yours, &c.,

JOHN B. VERITY.

31, King-street, Covent-garden, July 17, 1890.

"PROVING" OHM'S LAW.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The question which is raised by the communication which Prof. Lodge is circulating in consequence of the memoranda of Profs. Fitzgerald and Chrystal seems to need some care in handling, if it is not to increase the obscurity of the subject. If resistance is defined as the ratio of the electromotive force to the current which it produces, then the proposition that the electromotive force, divided by the resistance, gives (numerically) the current, is one which no more admits of discussion, nor needs experimental verification, than do the most elementary propositions of algebra. The experiments suggested by Maxwell, and tried by Prof. Chrystal, and those carried out by Prof. Fitzgerald, important though they are, cannot possibly be wanted to verify or prove Ohm's law. What they do go to verify or prove is, not whether the mathematical relation that bears the name of Ohm is true, but whether that property of an electric conductor which is called its "resistance" is, or is not, a constant. Now, it is common knowledge that the resistance is the function of at least one variable—the temperature; and it is quite a legitimate topic for inquiry, as Maxwell suggested, whether it is or is not also a function of another variable, namely, the density of the current passing through it. But why draw the line at these two variables? May it not equally be a function of such variables as the magnetic field in which the conductor is placed, the intensity of the illumination of its surface, the intensity of sound falling upon it, the intensity of the circumambient medium, the slope of temperature between its various parts, and the like? If it were found that the resistance of a conductor varied with any of these, surely one would not say that Ohm's law was false. One would simply say that the resistance was variable, and that if in Ohm's law one wrote the true value of the resistance corresponding to the circumstances, Ohm's law must then truly express the facts.

Now, whether this is granted or not, I invite the attention of the disputants in this matter to the very simple fact that for certain conductors, notably for iron and for bismuth, the resistance which they offer to currents of small density is assuredly not the same as the resistance which they offer to currents of large density, even if the temperature is artificially maintained equal in the two cases. It is known that these two metals—amongst others—when placed in a magnetic field change their resistance. The fact was first discovered by myself and Mr. C. C. Starling in the case of the metal tin; it was almost immediately afterwards independently detected by Righi; it has been measured by him, and also by Tomlinson; it has been made by Leduc and others the basis of a method of measuring the intensity of magnetic fields. Of the fact there can be no doubt. Neither can there be any doubt that when a wire of iron, or of bismuth or any other metal carries a current, a magnetic field is created circularly around the wire, partly outside it, also partly inside it. Also the intensity of this circular magnetic field within the metal depends upon the strength of the current. Hence it is *absolutely certain* that the resistance which an iron wire or a bismuth wire offers to a large currents, is different from the resistance which it offers to a small current.

But shall we, because we find that resistance is a function of another variable besides temperature, forthwith pronounce Ohm's law false? Surely the more rational mode of procedure is simply to acknowledge that resistance is not a constant.—I am, yours, &c.,

SILVANUS P. THOMPSON.

SHALL THE GOVERNMENT BUY UP THE TELEPHONE?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In speaking of the telephonic business you appear to me to have fallen into a contradiction and a misconception of the situation that, acted upon, will have very disastrous results upon electrical and all other progress. You first point out that telephony is rather dearer in England than in some other countries, because the Government lay a tax of 10 per cent. upon the companies who supply this mode of communication; and then, further on, you say that 10 per cent. is a very moderate charge to be allowed to earn 6 per cent. It cannot be to the benefit of anyone that telephoning should be more expensive than it naturally would be. If you approve of this 10 per cent. charged, you must approve of its results—dear telephoning. To bring it home to you, would you approve of reimposing the paper duty in the interest of the public, or in fairness to yourselves? Socialistic ideas seem so to have distorted our vision that the sound old Manchester school of political economy is discarded, as if its teaching had been exploded, which it has not. And then you regret that the Government, with its surplus, is in such a state of impecuniosity that it cannot see its way to buy up the telephone. Can it possibly be to the benefit of any one that an agency, which has shown its incapacity to compete with private enterprise even when handicapped with a 10 per cent. impost, should be entrusted with the conduct of this new enterprise? Let us just look back upon the action of Government upon the whole of the electrical field of enterprise, and see if it justifies the blind faith that we place in it. To begin with, Mr. Chamberlain snuffed out the electric light in England for ten years with his Electric Light Bill, a valuable service for which it is truly astonishing that he did not receive a peerage. Then, when we come to electrical traction, Mr. Reckenzaun declares, and all other authorities confirm what he says, that the greatest obstacle to its introduction and development is the Public Authorities. The story of the electric telegraph is a similar one, but is too long to go into. To return to the telephone companies, is it not quite clear that if they had not been hampered with this 10 per cent. tax they would have been in a much better position to develope and extend their business by lower rates of charge at which they would have had greater profits from the larger volume of business? Then, again, you praise the management of the directors of the telephone; and here lies the secret benefit of private enterprise, that it trains and educates an able body of men, and brings out their best qualities and abilities in a way that officialism does the very opposite of. Mr. Raikes, whose own performances are anything but satisfactory, you tell us has let the telephone companies know what he intends to do with them, which means that after letting them grow a bit, and showing him how to do the thing, he will rake them up and plant his officials in their place. The school of private enterprise was that in which Englishmen learned to be great and able; but although it served us splendidly, we are throwing it to one side in favour of the wretched one of officialism, that is incapable of progress, costly and inefficient, and offers a premium to sluggishness, apathy, incapacity in high places, and hopeless drudgery in the lower ones. It is truly sad to see a people who once believed in freedom turning back to bondage and hankering after the flesh-pots of officialism and Government bribes. Shall we ask the Government to buy us out altogether, that we may sit and vegetate; or to leave us free that we may live our own lives and fight our own battles?—that is the question.—Yours, &c.,

42, Richmond-terrace, South Lambeth, London, S.W., July 18, 1890. H. W. FAWCUS.

CHARLES MORRISON AND THE ELECTRIC TELEGRAPH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In one of your leaderettes last week (page 271), with regard to a reference of mine to Charles Morrison, you say that it seems doubtful "whether a telegraph has ever been constructed on this principle." Now, whatever may be thought of the value of Morrison's work, a question which I do not wish to raise here, I think there is very little doubt that he actually made the experiments described in the *Scots Magazine* for February 1st, 1753. It is true that his letter is vague on this point, but there was contemporary evidence that he did transmit messages short distances along wires by means of electricity. Indeed, there are good grounds for believing that his experiments made it necessary for him to leave the country, as his superstitious neighbours thought he was in league with the devil, and acted accordingly. He therefore went to Virginia, and efforts have been and are being made to trace his subsequent life there, but hitherto without success.—Yours, &c.,

R. MULLINEUX WALMSLEY.

Heriot-Watt College, 23rd July, 1890.

LEGAL INTELLIGENCE.

Stanley and Davies v. Milner and Co.

In the Manchester Civil Court last week, the case of Stanley and Davies v. Milner and Co. was before Mr. Justice Vaughan Williams and a common jury.

The plaintiffs, who are engaged in business as electrical engineers, sought to recover from the defendants, who are bleachers and finishers at Pendlebury, £136 for goods sold and work done. An installation consisting of 46 lamps was placed in the works, and the illumination was so complete that Mr. Milner expressed himself satisfied with it. Complaints were made later by the defendants that the installation was working improperly. The plaintiffs went and found that a man was in charge of the installation who knew nothing about it, and that the defendants' workpeople did not take due care of the machinery. The installation only consisted of 46 lamps, and of these not more than eight had been the subject of complaint. The defendants had pleaded that the whole installation was useless to them. Some of the wires also became corroded owing to the aciduous vapours that floated about the works,

Counsel for the defence submitted that the contract with the plaintiffs was for the wire to be of the best insulation, and of the highest conductivity of copper. The work was to be done in the best possible manner, and to be fit for a bleachworks. It was admitted in the plaintiffs' case that the wire inserted was not "of the best insulation and the highest conductivity of copper." That was a material point, because the fact that corrosion ensued showed that the material could not have been of the highest kind, or that it was fitted in the best possible manner.

The JUDGE said that on the contract as it stood it was extremely doubtful whether the sellers of the machinery contracted to supply machinery suitable with reference to the peculiarities of bleachworks. The whole question of the case was whether the plaintiffs were bound to supply machinery which should afford protection against these vapours.

Mr. FAWCUS, manager for the Edison and Swan Company, considered the wire not only unfit for bleach-works, but altogether unsuitable for electric lighting. He should not like to say that the machinery was useless, or to put any value upon it.

The JUDGE: What would be the most prudent thing for a man to do with that installation in your opinion? Would you take it out and get a new one, or alter it so as to get rid of the present defects?—I should certainly take it out and get a new one. The present dynamo might be used again, but new wiring is absolutely essential.

Mr. FLEMING having addressed the jury on the evidence, the Judge summed up.

After a brief absence the jury returned a verdict for the plaintiffs for the amount claimed; and judgment was entered accordingly.

Sharp and Kent v. Dane.

This was an action brought at Westminster County Court on Thursday last week by a firm of electrical engineers, to recover damages against the defendant for wrongfully absenting himself from his employment. The plaintiffs' case was that the defendant left work on June 26th last, about twelve o'clock in the day, without giving any reason, except that he declined to work under a foreman named Brittain.

The defendant was called, and said he had been very badly treated by the plaintiff firm. It was true he refused to work under a foreman named Brittain.

His HONOUR said he failed to see that the plaintiffs had sustained any damage by the defendant's conduct; but he would give them a verdict for the nominal sum of one shilling, but no costs would be allowed.

THE NORTHERN ELECTRIC WIRE AND CABLE COMPANY.—Last week Mr. Justice Kay heard an application on behalf of Mr. Edward William Hall of Park House, Bradford, Yorkshire, to correct the register of the Northern Electric Wire and Cable Manufacturing Company (Limited), by removing his name from the list as holder of 160 shares. This was an application under Section 35 of the Act of 1862, and the contention of the plaintiff was that he had not entered into a contract to take the shares in the Company; and that, in fact, at the time the allotment of shares was alleged to have taken place he had not applied for the shares, although he had a few weeks previously received from Blakey, Emmott, and Co., the vendors, a copy of the prospectus of the defendant company. After a lengthy legal argument, his lordship said it seemed to him that in the present case there was no binding contract. He went in detail through the facts of the case, and concluded by saying that the whole of the proceedings had been so grossly irregular that he must order the applicant's name to be removed from the register, and the £80 paid on the shares by the plaintiff to be repaid, with interest.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

TENDERS WANTED.—It will be seen by our advertisement columns that the Melton Mowbray Local Board invite tenders for lighting, during the ensuing year, the streets within their district, according to the specification, which can be seen at the office of their Surveyor. The tenders have to be delivered to Mr. Richard Barker, Clerk to the Board, not later than 3 o'clock on the 12th August next.

——— The Dirección General de Correo y Telégrafos, Madrid, will receive tenders up to August 11, 1890, for the installation and working of a telephone service in Las Palmas, Canary Islands.

BUSINESS FOR SALE.—Our advertisement columns contain notice of the sale, by private contract, of the valuable goodwill, with immediate possession, of a well-known manufacturing and retail business in mathematical and philosophical instruments, &c., in one of the best positions in Birmingham, which has been established over 38 years. Further particulars may be obtained of Mr. Arthur J. Pass, auctioneer and valuer, 50, New-street, Birmingham.

PLANT FOR SALE.—Our readers will find in another column particulars of a complete plant for 4,000 lamps, which is for sale, ready for fixing, comprising alternating-current dynamos and transformers (by Goolden and Co.), ammeters and exciters (by Goolden and Co.), and two 30 horse-power engines and boilers. Further information is to be obtained from the Secretary, Westminster Electric Supply Corporation (Limited), 4, Victoria-Mansions, Victoria-street, S.W.

PERSONAL.—Mr. Mark Bevan, who was for several years superintendent at Rio de Janeiro of the Western and Brazilian Telegraph Company, and for 4½ years in the service of Messrs. Siemens Bros., has established himself at West Bute-street, Cardiff, as an electrical engineer and contractor.

MESSRS. SIEMENS AND HALSKE.—Messrs. Siemens and Halske have opened a new factory in Apostelgasse and Hamburgergasse, Vienna, where electric cables of all descriptions will be manufactured.

ELECTRICAL INSTRUMENTS.—The contracts for the supply of electrical instruments to the London and North-Western Railway Company and for the Caledonian Railway Company for the ensuing year have been secured by Woodhouse and Rawson United (Limited).

THE ELECTRIC FITTINGS AT THE NEW HOTEL METROPOLE, BRIGHTON.—This splendid hotel was opened on Saturday last, and the electric light installation was much admired. A special feature of the installation is the "electric sunlights." In the principal suite of three large public dining-rooms these "electric sunlights" have been fixed within a very few feet of the ceiling of each room. They comprise a large handsome deep inverted embossed brass dish, within which are a number of glow lamps, the whole being surrounded by a fringe of cut-glass prisms, giving a most brilliant effect. These "sunlights" were manufactured by Messrs. Benham and Froud, of Chandos-street, in accordance with the ideas of the proprietors of the hotel. For the bed-rooms, portable table pillars, of four types, having opal shades covered with silk and lace, of tint to harmonize with the decorations, have been selected; and for the private sitting-rooms and vestibules, electroliers in brass, richly chased and burnished, with three to ten lights each in tinted and cut shades. Messrs. Benham and Froud are certainly to be congratulated on the effect obtained.

MESSRS. BEREND AND CO.—Messrs. Berend and Co. of 61, Fore-street, have sent us a book of pole-testing paper. Although not a novelty, this paper is very useful, and a few pieces may be kept in a purse or pocket-book. When moistened by the tongue, and touched by two wires, a red spot appears at the negative pole.

THE CONSOLIDATED ELECTRIC STORAGE COMPANY OF THE UNITED STATES.—This Company announce that they are manufacturing the Julien storage battery, and are exclusive licensees for the United States of the storage battery patents of Charles F. Brush.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The thirty-sixth half-yearly ordinary general meeting was held on Thurs day, July 17, 1890, at Winchester House, Old Broad-street, London; Sir John Pender, K.C.M.G., in the chair.

The SECRETARY (Mr. George Draper) read the notice convening the meeting, and the minutes of the last general meeting; and the report having been, at the request of the meeting, taken as read,

Mr. CLARKSON (a shareholder) said: In order that there may be no mistake, I wish to inform the Chairman that at the proper time I shall have something to say, and I therefore ask him not to pass the resolution without giving me the opportunity of speaking.

The CHAIRMAN: Now, gentlemen, I will, as has been usual on these occasions, make some remarks on the report and give you some further information as to the working of the system during the past six months. Our revenue for the half-year ending March, 1890, amounted to £424,023 as against in the corresponding half-year of 1889 (which owing to the activity in South Africa was an exceptionally good one) £435,932, showing a decrease of £11,909. But the balance brought forward from the September half-year accounts was £61,151 as against £36,616 in the corresponding period of 1889, being an increase of £24,535. We have, therefore, an increased available amount to deal with of £12.626. It will be observed that our dividend on Direct Spanish shares is £246 more than

Digitized by Google

in the corresponding period ; and I have much satisfaction in calling attention to the dividend which we have received from the African Direct Company, viz., £1,500, being at the rate of 4 per cent. per annum for the half year to 31st Dec. last. The African Direct Company was formed to carry out an important work, viz., the establishment of telegraphic communication with the British Colonies on the West Coast of Africa ; but the local traffic of the line was very small, and even with the subsidy received from the British Government the Company was unable to meet its working charges. Now, however, that it has a share in the South African through traffic, the African Direct Company is showing a small profit, and we may hope that in future our investment in this Company will be a fairly remunerative one. The total working expenses for the half-year to March, 1890, amounted to £98,477, as against £92,448, being an increase of £6,029, the details of which are as follows:—General expenses in London £8,726, against £7 988 or an increase of £738. This is in salaries, office expenses, rent, stationery, and printing, &c., consequent upon the continued development and expansion of the Company necessitating additional staff and accommodation. Working expenses at stations amounted to £72,677, against £68,545, or an increase of £4,132, the principal item of which is in the salaries of our station staff at home and abroad, which was fully explained and approved at the last general meeting. The number of staff at stations in 1890 was 637, against in 1889 582, or an increase of 45. On the other hand, several of the items under Abstract "B" show a decrease, namely—repairs and renewal of furniture at stations £1,109, repairs to stations £423. Depreciation of cable stock is also less by £654. Repairs to cables amounted to £47,520, against £48,665, or a decrease of £1,145. Full details of the expenses of the ships, &c., and cables used for repairs, will be found on reference to Abstract "C" in the accounts.

You will find as a charge against reserve fund a sum of £5,397, for loss, owing to a robbery at Athens from our banker. He received the money too late to remit it, and between that time and the next morning it was abstracted. We have not yet been able to recover the money, but we are on the track still. Whether our efforts will ever be successful it is very difficult to say. I may mention that our banker there was agent of the Company in one way and another for 18 years. He was a man who had a very high character, and we had known him personally. Unfortunately, when this robbery took place, he was on a sick bed, and he has since died.

After providing for all expenses and interest charges against revenue, we are able to recommend a final dividend at the rate of 5 per cent. per annum, and a bonus for the year of 1½ per cent., making a total distribution of 6½ per cent. on the ordinary shares. We carry £125,000 to the general reserve fund, which now amounts to £607,000.

Now, gentlemen, when I last addressed you, I referred to the West Coast of African system as being fully completed, and I said I believed we should have important results. I am glad to confirm that opinion to-day. The African Direct Company is paying 4 per cent., and I hope in another year you will see an increase on that dividend. The West African Company are paying a dividend of 5 per cent., and I also expect to see an increase in the case of that Company if the state of things which has hitherto existed in Africa continues. Altogether we are now in a position to meet all the requirements in the course of the development of that dark territory which has been so much before the world in the last few years. We are, as I have said, I think, on a previous occasion, ahead—we are prepared to do our part in connecting that new world with the old, and I hope it will be not only in the interests of civilisation that we shall do so, but materially in the interests of our shareholders.

I also said at our last meeting that we had had some little trouble in Egypt, and that these settled I looked forward to a better state of things in that country. I mentioned at the same time that I was about to proceed to Egypt, which I did ; and the result of that visit, I may safely say, has been that we have settled our affairs with Egypt in such a satisfactory way that it will very materially benefit the Company, and at the same time benefit Egypt also. I may add that our relations with Egypt are now of a most satisfactory kind, and are likely to be so for many years to come. I also referred to the Telegraph Conference which at that time was coming on. I said that at Berlin we had had to make considerable sacrifices. The Paris Conference took place two months ago, and you were there very ably represented. There was no point that was not fairly argued and discussed ; and I am bound to say that the treatment of us by the general body of the Conference, representing the different Governments of Europe, was upon the whole very fair and very satisfactory to the Company. I think I mentioned that we have no vote at these Conferences. All our influence has to be brought to bear by putting strong sterling facts before the different representatives, and as a rule those facts have been generally fairly accepted, and dealt with ; and I think I may say, without fear of contradiction, that the Company's relation with the existing Governments of Europe in telegraph matters never stood higher than at the present time. I think the Company is indebted to our staff for the way in which our affairs were conducted at the Conference. Every member of the staff there did his best, and I think the result has been that we have come out of that Conference more satisfactorily than we have come out of any previous Conference. For the next five years, at all events, we are free, and I hope the comparatively small reduction of tariffs which have been made will be speedily recouped. We have to compete in the Mediterranean with different land systems, but as regards the reduction which has been made, I have no hesitation in saying that, having watched the progress of telegraphy, before I meet you again—or, at all events, before another year passes—we shall have recouped ourselves for any reduction of tariffs by an increased number of messages.

I may also mention another point, which I think very important, because it is not always very easy to deal with Governments. Governments have a great deal of red tape in their system of conducting negotiations ; and in our telegraph system we have as little red tape as can be used, for it would destroy our system. We have to be prompt in everything we do as to any telegraph negotiations. I am pleased to say that our relations with India were very materially improved at the Conference. India was represented there by a man of considerable intelligence, who thoroughly understood the subject ; and there was a give-and-take between the Company and the Government which, I think, has been highly beneficial to both. We have had, as I have just mentioned, to submit to certain reductions to Spain, Portugal, and Gibraltar ; but I hope they will be met by a considerable increase of traffic.

I have received a letter from an honourable shareholder—and I always like to pay attention to any letter I receive—in which he compliments the Board on their general good management, but he also says, looking to the large sum we are carrying forward, he thought the bonus ought to have been larger to-day than we have decided to declare. But changes have taken place since I last had the pleasure of meeting you. We know that a reduction will be made, and that what we shall lose will not be recovered within a year through the changes that have taken place since I last met you, and more particularly with regard to the Australian tariffs. We are going to make a remarkable reduction there, or, rather, the Eastern Extension Company are going to reduce their rates ; and whatever they do on the one side, we have to support on the other, more or less. Therefore we are parties to the arrangement with the Eastern Extension Company whereby they are going to reduce the tariff to Australia from 9s. 4d. a word to 4s. ; but in reducing it to that point we shall have the guarantee of the Governments of those colonies that they will pay one-half of any loss that may be incurred by the reduction. You will therefore have a stock which is, at all events for a period, partly guaranteed by the Australian Governments, and this should add materially to the value of our holdings. This reduction in tariffs must necessarily lead to a very considerable extension of our system generally, and our Red Sea cables have been in operation for some considerable number of years now.

Sir JAMES ANDERSON : Twenty years.

The CHAIRMAN : Nearly twenty years ; and we feel that we shall not be doing our duty to you or to the telegraphing public if we did not prepare at once for the increased traffic that must arise out of this great reduction of the tariff to Australia. We have, therefore, without hesitation, decided to lay another cable in the Red Sea from Suez to Aden. That cable will cost us at least £250,000. Now, looking forward to maintaining the respectable dividends we are paying at present, we think it is better, as far as we possibly can, to pay for that cable—or mainly to pay for it—out of our reserve fund ; and we have therefore increased our reserve fund to-day, as you observe, by a very considerable sum, so as not to add to our capital in extending our system to meet the growing demands upon it. I hope you will approve of that policy. (Applause.) I think it adds more to the value of your property by dealing with the matter in that way than by increasing your capital and eventually reducing your dividend.

I think these are the different points I wish to draw your attention to ; and the various remarks I have made in my statement will, I think, satisfy you that we are in a sound and satisfactory position. The amount that we are carrying to reserve is a very large one, and I have a great deal of sympathy with the gentleman who wrote this letter. Still, I am quite sure, when he has received the explanation which I have now made to you, he will prefer a trifle less dividend, feeling that he has a stronger security. I shall now move the resolution, but before doing so if any gentleman in the hall desires to make any remarks on the report or on the observations which I have just made I shall be very pleased to listen to him.

Mr. CLARKSON, a shareholder, having addressed the meeting at some length,

The CHAIRMAN said : Gentlemen, you have heard a very remarkable jumble of ideas, a great deal of it ancient history, quite irrelevant, and showing perfect ignorance on the part of the speaker. I therefore, with your permission, pass it over without further remark (hear, hear).

No other shareholder rising to address the meeting, the CHAIRMAN put the following resolution, which was seconded by the Marquis of TWEEDDALE, and carried unanimously :—

"That the printed report and accounts of the Directors to 31st March, 1890, submitted to this meeting, be and the same are hereby received and adopted. That a dividend on the Preference shares of the Company to 30th June, 1890, at the rate of 6 per cent. per annum, be paid less income-tax : and that in accordance with the Directors' recommendation a dividend be and is now declared of 2s. 6d. per share, with a bonus of 3s. per share, both free of income-tax, on the ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of 6½ per cent. on those shares for the year ended 31st March, 1890."

The CHAIRMAN : That is the only resolution I have to submit to you to-day, and I am very pleased to find that you have accepted it so unanimously.

Mr. JAMES GIBB : I trust that you will not regard it as an impertinent intrusion into relations more sacred than business relations if I express for myself, and I am quite sure for the body of shareholders here present, our very deep sympathy with you, Sir, in the loss you have sustained by the death of Lady Pender. We have met you here from time to time, and we cannot, I am quite sure, have had other feelings than those of the greatest respect for you, and we have felt extremely for you in the present very trying circumstances. I will, therefore, ask the meeting to pass a resolution which I shall propose, recording a vote of condolence with Sir John Pender and his family in their present great affliction. I should like also to express our obligation to Sir John Pender, Sir James Anderson, and the other gentlemen who so ably represented the Company at the late Conference and have so well guarded our interests.

Mr. JOHN NEWTON : I hope I may be permitted to second this resolution. I may claim to be in a position to appreciate the value of the Chairman's services to you, and for the way in which he has opposed those on this

Digitized by Google

side of the table, of whom I used to be one of the most prominent. Still, by the action I took I think I have benefitted the Company. I think that the manly way that you have struggled for the interests of this Company at all the Conferences which have been held, have given us such confidence and sympathy that you will not think it inappropriate that we should express to you on this occasion our regret at the loss which you have sustained. Moreover, we see that, notwithstanding this overwhelming trouble, you are at your post on this occasion. I second the resolution.

Dr. WALLER: I am very glad to find that these gentlemen have expressed the sympathy which I feel, and which is felt no doubt by every one who is present. It is an occasion of deep sympathy with me at least, and I am sure I am not exceeded in this feeling by anyone present. I have had the honour and pleasure of knowing Sir John Pender for twenty years, and have received from him from time to time the greatest courtesy and kindness, and none of the shareholders can feel more deeply than I do the loss which he has sustained. I believe this feeling will be perfectly unanimous. There are some domestic matters in which sympathy is better expressed by silence; and, therefore, I will not say another word except that I believe I represent every individual here in expressing our deep condolence with Sir John Pender in his trial.

Mr. GIBB: The resolution is as follows:—

"*The shareholders of the Eastern Telegraph Company (Limited), desire to express their sincere sympathy with Sir John Pender and his family in their present severe affliction.*"

The motion was agreed to unanimously.

The CHAIRMAN: Gentlemen, this is unexpected. It is, nevertheless, very soothing to me, and is most sympathetic on your part. I have lost the companion of my life—one who encouraged me in every good work I was engaged in. She was a large shareholder in this Company, and took a very deep and warm interest in everything which promoted, I may say, human progress. I thank you most deeply for your sympathy. I do it, not only on behalf of myself, but also on behalf of my family. Everyone of them has felt this very severe loss. We have felt that the sunshine has departed from our home; but, nevertheless, we believe that the noble example she set to us all will be a model for us to follow in our path through life. I thank you for the way in which you have adopted the report, and for the vote which you have awarded the Chairman, Sir James Anderson, and the Board. I can only say, from a most perfect knowledge of the wishes, the desires, and abilities of the gentlemen who sit on this side of the table, that they are proud of the position they occupy. They are proud of it because this system has become, probably, the most useful and civilising institution that exists on the face of the earth at the present moment. The work that we have done in promoting political, commercial, and social progress throughout the world cannot be measured. Therefore, whatever may be said, there is to be said for the Board that they are doing their duty faithfully and honestly, and the shareholders are reaping the reward of their exertions.

The proceedings then terminated.

The South of England Telephone Company (Limited).

The seventh ordinary general meeting of this Company was held on the 18th inst., at Winchester House, 50, Old Broad Street; Mr. D. Owen Bateson presided.

The SECRETARY (Mr. Fred. L. Robinson) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen,—My first business to-day is to explain why the report and balance-sheet of the Company have been delayed this year beyond the time they have usually been issued. Many of you are aware that our licence from the Post Office is only terminable at periods of seven years, by the Postmaster-General giving us six months' notice. The first of these periods expires on the 31st December this year; and as notice has not been given us the Company have now another term of seven years of life before them. It was thought undesirable that the condition and progress of our business and our figures should be produced while this was in abeyance; but as soon as the Postmaster-General announced that he had no intention of moving in the matter we have lost no time in handing our report and in calling you together. I may add that there has been no delay on our part, as our books were balanced and our accounts made ready for the auditors within about six weeks of the termination of our year, viz., April 30th. I have no doubt but that next year we shall revert to our usual time of holding our annual meeting. I should also like to state why we did not pay our Preference dividend at the beginning of May, as in former years. Some of our shareholders expressed a doubt as to whether the plan we had previously adopted was correct, arguing that though right enough to pay an interim dividend on an estimate of profits, it was hardly businesslike to make a final distribution before the correct balance had been ascertained and audited. This view being considered reasonable by your Directors, they have adopted it. Your Directors have nothing to complain of as to the progress of the business. The increase is not very rapid, but it is continuous and steady, and considering the somewhat bare pasture which we cultivate, we have, we think, fair reason to be satisfied. I am sorry to say that the National Company apparently do not see their way to admitting our subscribers to their system; this debars us from exploiting the most valuable part of our district, viz., that which lies within a radius of 20 miles or thereabouts from London. There are many residents and firms who are most anxious for this communication; and I do not think this connection of the two systems can be very long delayed, as I am sure it would be much appreciated, and, what is more to the interest of the telephone companies, it would be extremely profitable. Our trunk line system in East Kent will shortly be completed by the erection of a route between Ashford and Canterbury. This will enable the former town to communicate with almost all the centres of business and sea-side towns in the district. We have to thank Lord Winchilsea for granting us the wayleave through his large estate at Eastwell Park, and thereby facilitating our running this line. The cost of wayleaves is increasing year by year; though as a rule they are accorded to us without much difficulty, we are occasionally squeezed unmercifully. When we find this is being done we prefer altering our routes, if possible, even at considerable extra expense, rather than give way to undue pressure. The rating question, too, is becoming a serious matter for telephone companies, and in many of the towns in which we work this question has been raised. In Brighton we appealed to the Quarter Sessions against what we considered an excessive assessment, but unfortunately did not get it reduced. It ought really to have been carried to the Queen's Bench for a final decision; but as the parent Company positively declined to bear any portion of the expense for so doing, we did not think it well to spend any more of your money in a matter that, being for the general good, we considered ought to be paid for out of the common purse. No doubt the question will come up again elsewhere, and will have to be fought out. Our hope is that this will not occur in our district. As regards our accounts, those of you who have analysed the figures will have seen that our gross rentals have increased £3,676. This is about our usual average. This year, however, the shareholders derive no benefit from this improvement, as our auditors have made a great point of our carrying a much larger proportion of our wages and office expenses to revenue than our auditors last year thought necessary. It was considered, too, that the reserve ought to be increased, as this item has not been altered for some years. No doubt they were right to some extent, as the older the Company grows there must of necessity be an increased amount expended on repairs of lines, altering routes, &c. This we quite admitted, and provided for in the balance-sheet we submitted; but our auditors were apparently resolved that all our increase for the year should be placed to maintenance. Your Directors thought, and still think, that so large an addition as £3,753 to maintenance was unnecessary and inequitable; but as a clean certificate was refused us, and we were threatened with a contentious meeting if we did not, we thought it well unwillingly to agree to the inevitable, and present the figures which you have before you, leaving the matter in your hands. There is little doubt that the alterations strengthen the financial position of the Company; and though for a time it is probable that the selling value of the ordinary shares may be depreciated to some small extent, that of the Preference shares ought, at least, to be maintained, as they are, to my mind, a steady and reliable security. I do not think there is any other matter in the accounts that needs explanation; all the figures seem to me to be easily understood. However, I shall be glad to make anything clear that appears to be in any measure obscure.

A SHAREHOLDER asked whether there were any negotiations pending between them and the National Telephone Company with a view to buying up the Company.

Another SHAREHOLDER stated that he noticed the National Company, in their report, valued the shares they hold in this Company at 5s. each. He hoped the Directors would not enter on any negotiations at such a figure or anything like it.

The CHAIRMAN replied that they had never been approached on this subject, nor had they asked any price yet for the shares. The Chairman of the National Telephone Company had stated that it would be necessary to buy up this and the Western Companies, and that it was entirely a question of price. That gentleman, however, had not said that there were any negotiations pending, as the shareholder who asked the question seemed to think. When the time came they would be glad to receive a fair offer, but of course nothing would be done in the matter without consulting the shareholders, for which they would be called together. He concluded by moving:—

"*That the report and accounts for the year ended 30th April, 1890, now presented, be adopted and passed.*"

Mr. ALEXANDER MACGREGOR seconded the resolution, remarking that the placing of a large sum to the reserve account was a wise policy, and would conduce to the interests of the Company.

The resolution was carried unanimously.

The CHAIRMAN next moved:—

"*That a dividend at the rate of 6 per cent. per annum for the half-year ending 30th April, 1890, on the Preference shares be now declared payable on the 19th inst., making 6 per cent. for the year.*"

Mr. CHARLES BILLETT seconded the motion, which was carried unanimously.

The CHAIRMAN moved:—

"*That a dividend at the rate of ½ per cent. per annum on the ordinary shares be now declared, payable on the 19th.*"

Mr. BILLETT seconded the resolution, which was agreed to, *nem. con.*

Mr. WILKINS asked what interest was paid on the amount received in anticipation of calls.

The CHAIRMAN replied that it was a matter of bargain, but in all cases they had received the money at 5 per cent

Mr. MARSHALL proposed, and Dr. ELLIS seconded, the next resolution as follows:—

"*That the sum of £200 be paid to the Directors for their services during the year ended 30th April, 1890.*"

The resolution was carried unanimously.

On the motion of Mr. BILLETT, seconded by Mr. MACGREGOR, the Chairman was re-elected to his seat at the Board; and the CHAIRMAN having briefly acknowledged his re-appointment, Mr. J. Weise, the shareholders' auditor, was re-elected, and the proceedings terminated.

Digitized by Google

United River Plate Telephone Company (Limited).

The fourth annual ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on the 22nd inst.; under the presidency of J. Irving Courtenay, Esq.

The SECRETARY (Mr. J. Owen Unwin) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: It is now my duty, in the absence of Lord Thurlow, to address some observations to you before I move the adoption of the Directors' report and the balance-sheet. My task on this occasion is not an easy one, for to all those who are interested, and they are many, in the Argentine Republic, the financial position of affairs in Buenos Ayres cannot but be a matter for much anxiety; but from the best information I can get, and you are aware that this Company is fortunate in numbering amongst its Directors several gentlemen who have spent a good part of their life in the River Plate, and who are, therefore, thoroughly acquainted with the country, I have a full belief that, with a prudent administration of its affairs, the natural resources of the country are so great that it will rapidly surmount its present difficulties. The gross income for the year shows a large increase, as it amounts to £108,612. 2s. 7d. for the year ended the 31st March, 1890, as against £81,866. 2s. 4d. for the previous twelve months. These figures need no comment; they speak for themselves, and show how largely our business has grown and developed during the past year. There has been a considerable rise in the working expenses, which has been caused mainly by a large increase in wages and an increase in the cost of materials. We have fortunately avoided any serious dispute with our *employés*, but, as in the case of other River Plate Companies, the depreciated currency has rendered a considerable increase in the wages account absolutely unavoidable, while the cost of our materials has naturally been greater. There has also been some increase in taxation. These several increases in expenditure have caused an increase in the percentage of working expenses. There is also a special item of expense this year, caused by the repairs rendered necessary by a cyclone in Rosario in December last. The grave loss of the Company, however, as you will observe from the profit and loss account, is the loss on exchange, which is the cause of your reduced dividend, and is a matter entirely beyond the control of the Directors; it amounts to no less than £22,334. 17s. 1d. as against the loss last year of £14,689. 6s. 8d., or an increase of £7,645. 10s. 5d. The total loss on exchange is, therefore, about 8 per cent. on the paid-up capital. The result, after paying all working expenses, debenture interest, and general charges, both in the River Plate and in London, is a profit of £34,198. 6s. 5d., from which deducting the loss on exchange, viz., £22,334. 17s. 1d., there remains a net profit of £11,863. 9s. 4d., which, with the balance from last year of £1,210. 7s. 2d., amounts to £13,073. 16s. 6d. We paid an interim dividend of 2 per cent. (£5,800) in January, and we recommend a further payment of 1 per cent. out of the balance. We propose to carry £2,000 to depreciation and renewal fund, which will then stand at £9,000, and to carry forward the balance of £2,373. 16s. 6d. In view, then, of the abnormal position of business in the Argentine Republic, which has existed for some time past, I think you will agree with me in considering the results obtained to be fairly satisfactory, and I hope that you approve of the policy of the Directors in carrying forward a substantial balance to next year. I will now proceed to point out a little more in detail some of the encouraging features in connection with the Company's business in the Plate. At the date of the balance-sheet, namely, March 31, 1890, the number of subscribers in Buenos Ayres and Rosario was over 5,000. You will remember that the Company commenced business with about 3,000 subscribers. There has been, as might be expected during such a crisis, a number of people who have given up their telephones; but, on the other hand, there has been every month a steady influx of new subscribers, and the business of the Company has shown, in spite of the financial crisis, a remarkable vitality. I have no hesitation in saying that this most satisfactory feature has mainly been brought about by careful and vigilant administration, and by the excellence of the service the Company gives to its subscribers, both at Buenos Ayres and Rosario, and in this connection I will read an extract from a letter from one of our Buenos Ayres representatives, in which he says:—"We are giving a service such as we can safely say has never been given in Buenos Ayres before; of course, we have complaints, but they are brought down, we think, to a minimum, and are neutralised by the many expressions of satisfaction that we hear on all sides." I am sure you will agree with me in thinking that we may congratulate ourselves on having such painstaking and zealous representatives as Messrs. Fels and Krabbé at Buenos Ayres, and Mr. Chappell at Rosario. The Directors have during the past year carried out successfully what they hinted at in their report of 1889, and have raised the rates of subscription, with the view of meeting to some extent the increased expenses and charges incidental to the condition of the currency and business generally in the Plate. The capital outlay for 1889-90 is £7,297. 14s. 11d. less than it was in 1888-89, even after deducting from the outlay of the last period the cost of the purchase of the Rosario business; and I may here remark that the Directors have not overlooked the question of the construction of the Rosario trunk line when a favourable opportunity presents itself. The issue of Five per Cent. Debenture Stock, and the conversion of the Seven per Cent. Debentures, as authorised by the Extraordinary General Meeting in January of this year, has been satisfactorily carried out, and was evidently appreciated by the shareholders. I believe I have now touched upon most of the important points, but if there are any upon which the shareholders desire further information, I shall be happy, as far as lies in my power, to meet their wishes. I cannot conclude without expressing my confidence in the future of the Company; I think it is evident that its business is steadily improving, and, therefore, when this crisis has passed away we shall reap the fruits of the solid progress that has been made, and the substantial position that we have been able to reach, in spite of the financial obstacles that we have had to encounter and are encountering; and I may add that our receipts for the first quarter in the new year, April to June, have, as we know by telegram, been larger than in any previous quarter since the Company commenced. I now beg to move:—

"*That the report and accounts submitted to the meeting be, and they are, hereby received and adopted by the Company, and that the Company declare the dividend recommended in such report.*"

Mr. FRANK W. JONES seconded the motion.

Mr. PEEL congratulated the Directors on the present position of the concern, the progress of which was clearly evidenced by comparing the figures of the past year's working with those of the previous year.

Dr. ELLIS said he noticed that there had been a very large increase in the business of the Company, but he wished to know whether this increase had been caused by the acquisition of the Rosario business. Last year they paid a dividend of 6 per cent., whereas he calculated that this year they would only have had enough to pay 5 per cent. if the rate of exchange had remained the same. They had a depreciation and renewal fund, and he thought that the expenses caused by the cyclone, to which reference had been made by the Chairman, should have come out of this fund, and that they ought not to hear of such an event causing an increase in their working expenses. He felt sure, with the previous speaker, that the best had been done for the shareholders, and that they had no cause of complaint. That that, too, was the general feeling of the shareholders was clear by the small number who had attended. He had certainly expected to see more shareholders present in face of the reduced dividend; and the small attendance clearly proved the confidence of the shareholders in the Board.

The CHAIRMAN: The Directors are very much obliged to Mr. Peel and Dr. Ellis for the kind expressions they have given utterance to. Of course the Rosario business does go into the accounts; but, quite apart from the Rosario business, there has been a considerable and very satisfactory increase in the Buenos Ayres business. I do not think it is advisable to give the precise figures of the increase in our new subscribers. As I have said, we have had to increase the rates of subscription. We were told that this would do a great deal of harm, but I am glad to say that it has by no means caused the harm which some people anticipated. There has been a considerable increase in the number of the subscribers, and I think that it is an increase which we have every reason to be satisfied with in the circumstances which have prevailed, and the state of business in the country. Not only did a rise of wages occur, but there was also an increase in the cost of material. There is no doubt that this has told on us very decidedly. Supposing the rates had not been increased, we should not have done so well in regard to the question of dividend. I took note about the observation that was made as to charging the expenses of damages done by cyclones to the depreciation and renewal fund; but I hope we shall have no more cyclones to charge against anything. We want, however, to have a good depreciation and renewal fund, and we thought it right to charge the expenses of this particular storm against the revenue. We will bear in mind your remarks on a future occasion, but I think we ought to have a strong reserve fund. I think we can see from the tone of the gentlemen who have spoken and the feeling of others with whom we have communicated that they approve our cautious policy in trying to build up this Company. We all feel the loss of dividend, and I should have been very pleased if we could have paid more. I am, however, glad that you approve our policy of not dividing up to the hilt. He then put the resolution in the usual manner, and it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Dr. ELLIS, the retiring Directors, Lord Thurlow and Mr. Frederick Green, were re-elected; as were also the Auditors, Messrs. Cooper Brothers and Co, on the motion of Mr. BISHOP, seconded by Dr. ELLIS.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

Exeter Electric Light Company (Limited).

The second annual meeting of the shareholders of the Exeter Electric Light Company was held at the Company's works, New North-road, on Tuesday; Mr. W. H. Ellis presiding.

The following is an abstract of the Directors' report:—"The numerous difficulties which are inseparable from the commencement of every Electric Light Supply Company have been successfully overcome. The property which your Directors secured on such advantageous terms as a site for the central station has been thoroughly adapted and fitted up for the purpose, for which its position makes it most valuable. The plant laid down, which has been selected with great care by Mr. Massingham, the Managing Director, and the Electrician-in-Charge, is of the highest possible efficiency and in excellent working order, as is testified by the fact that during the last six months no customer has been deprived for a single hour of the light for which he pays. The accounts show a profit of £165. 6s. 7d., which your Directors recommend should be carried forward. That any profit should have been made must be considered satisfactory, seeing the short time that the station has been in anything like working order, and that neither the arc nor incandescent dynamos are yet being worked to their full capacity. The Company being now well established, and the supply of the electric current perfect, there is every reason to expect that during the next six months all the additional lights which the machines are capable of supplying will be taken up by customers, which would produce a good dividend, to be augmented as the demand for light increases and additional plant is laid down. It has been considered desirable to apply to the Board of Trade for a Provisional Order authorising the Company to supply electricity in Exeter, and the necessary

Digitized by Google

preliminary notices have accordingly been given. This order will place the Company in a more advantageous position for extending its operations, and will empower it to place the mains underground."

The CHAIRMAN moved the adoption of the report, which, he said, they must all feel to be exceedingly satisfactory, considering the short time the Company had been running. He could not help thinking that everyone who had the chance of having the electric light would do so when they considered the great advantage there was to be derived from using it in point of health.

Mr. MASSINGHAM seconded, and said he considered the report was highly satisfactory.

The motion was agreed to; and Mr. Knill having been re-elected auditor, the meeting closed with votes of thanks to the Chairman and Directors generally.

Crompton and Co. (Limited).

The second annual general meeting of the members of Crompton and Co. (Limited) was held at the City Terminus Hotel, Cannon-street, on Monday last, under the presidency of Mr. R. E. B. Crompton.

The SECRETARY (Mr. Francis R. Reeves) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen,—I feel very greatly my position in having to take the place of my lamented friend, Lord Torrington, who died since our last meeting. The matter is a personal one to me, because he was my greatest friend in the world; and his loss to you also is very great, for he was a man who took a keener interest in your affairs than I have ever witnessed any other Chairman do. We are finding it extremely difficult to replace him. At the date of the last meeting the whole of your Preference shares were not placed. There still remained 1,200 of them unallotted, but these we placed shortly after that meeting. Thereupon, it became the duty of the Directors, in accordance with the promise contained in the prospectus, to make an application to the Stock Exchange for a quotation of and settlement in the Preference shares. The Stock Exchange Committee found the papers and books in order, but it required an unimportant alteration to be made in the Articles of Association. To effect this alteration the shareholders were called together, and the necessary special resolution having been passed and confirmed the Stock Exchange Committee granted the application, and the shares are now quoted in the official list. There have not been many sales of shares during the year, judging from the transfer books. The explanation of this is that the shares are firmly held, and that the shareholders do not wish to part with what they believe to be a good dividend-paying property, and moreover they appear to be worth more than their present list quotation. The business of the Company has increased very largely during the year, and has compelled the Directors to look for more capital for the increase of plant at Chelmsford and elsewhere, and for increasing the working capital. They therefore decided to exercise the borrowing powers vested in them by the Articles, and to issue Five per Cent. Debentures to the amount of £50,000. These debentures are secured by a deed of mortgage vesting all the property of the Company in trustees for the debenture holders. In the prospectus of the first issue we offered £25,000, which has all been applied for; but the Directors now propose to offer the remaining £25,000 among the shareholders; and a circular to this effect will be sent out with the dividends this evening. The debenture debt is the only charge upon the property. The shareholders will see by the statement before them that the profit of the last year was £10,610. 1s. 7d., which is an increase of £2,000 over the amount earned last year, and about £4,000 greater than the average profit for the six years preceding the formation of the Company. This result must be considered fairly satisfactory. After the payment of the interim dividends, providing for debenture interest and other charges, and setting aside £500 for doubtful debts, there remains £5,530 available for dividend; and out of this sum the Directors propose to pay 7 per cent. per annum on the Preference and 5 per cent. per annum on the ordinary shares of the Company, carrying the balance, £474, forward. As I have already stated, the increasing business of the Company has necessitated capital expenditure both on buildings and plant, as well as on tools and extensions at Chelmsford and the starting of London works. The Company have also taken over a portion of the property which was leased to Messrs. Crompton and Fawkes, which is immediately available for the extension of the Chelmsford works. In London during the past year we had the good fortune to secure very large orders from three of the most important supply companies. The nature of these orders is the supplying and fixing of central stations, and of a complete system of underground mains, extending over 40 or 50 miles of London streets. During the early portion of last year we worked with a separate staff from temporary premises on the Kensington Court estate; but as these premises were no longer available the Directors thought it advisable to lease convenient ones on a longer tenure. They have taken a lease of No. 1, Lillie-road, West Brompton. These premises are sufficiently large and convenient for our purpose. They are now in process of being fitted up, and are nearly completed, and they are the head-quarters of the engineering staff in connection with these large West End orders. The principal feature of these orders is that there seems to be a fair chance of a good profit being made on them, and the risks in connection with them are not large. The order books of the works are full of our own specialty—dynamo machines, switchboards, and that class of plant. Further than this, the general prospects of orders are better, I think, than I have ever known them since I have been in the electric light business. I think we may congratulate ourselves on the extremely good feeling which is prevailing between ourselves, our staff, and workpeople. We have succeeded in organising piecework on the most considerable scale that we have yet attempted, and that without meeting with the difficulties that other engineering firms have had to contend against. I think that a great deal of this is due to the tact and good management of our Chelmsford managers, who have succeeded in carrying out this difficult work without in any way causing ill-feeling. We know that this very delicate subject of piece work has been the bone of contention which has caused so many strikes all over the country. I need hardly tell you gentlemen, that a successful work of this kind is a great step in advance, as it enables us to keep accounts and to know the cost of our work with much more accuracy than was possible to be the case with the greater part of the work when done by day labour. As to the annual statement of accounts themselves, I do not think that there is anything which calls for special comment; but should any shareholder desire any further explanation, I shall be glad to give it. I will conclude by moving—

"*That the report of the Directors and the audited statement of accounts for the year ending March 31, 1890, be, and the same are hereby, approved and adopted.*"

Sir CHARLES GRANT seconded the motion.

Mr. T. R. TUFNELL expressed his great satisfaction with the way in which everything was conducted at the Company's offices. He called several times on various matters, and the explanations were perfectly satisfactory.

The SECRETARY, in answer to Mr. COX, said that the accounts of the Australian Company had not yet reached England, but one of the managers was on his way with them. Meanwhile, they had learned that the accounts showed a satisfactory profit.

The resolution was carried *nem. con.*

The CHAIRMAN moved, and Mr. C. F. TUFNELL seconded, the next resolution, as follows:—

"*That a dividend at the rate of 7 per cent. per annum for the half-year be declared and paid on the Preference shares of the Company.*"

The motion having been unanimously approved,

The CHAIRMAN moved, and Mr. GIBSON seconded:—

"*That a dividend at the rate of 5 per cent. per annum be declared and paid upon the ordinary shares of the Company.*"

The motion was agreed to *nem. con.*

The CHAIRMAN moved:—

"*That Sir Charles Grant be, and he is hereby, re-elected a Director of this Company.*"

I can hardly say how much the Managing Directors were indebted in the past for the advice and assistance of Sir Charles Grant, who has acted as our Chairman since the death of Lord Torrington. I am occupying this position to-day chiefly on account of my long connection with the business, and because of my intimate acquaintance with the details; but Sir Charles Grant has been a powerful and steadfast man, on whom we Directors have had to rely, and I should feel it very much if he left the Board of this Company.

Mr. ALBRIGHT seconded the resolution, which was carried unanimously.

On the motion of Mr. TUFNELL seconded by Mr. DRUMMOND, the auditors, Messrs. J. H. Duncan and Co., were re-appointed; and a vote of thanks having been accorded to the Chairman and Directors, the proceedings terminated.

Anglo-American Telegraph Company (Limited).

Report of the Directors to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad-street, E.C., on Friday, the 1st of August, 1890, at two p.m.

The total receipts from January 1st to June 30, 1890, including the estimated balance of £2,247. 12s. 8d. brought forward from the last account, are estimated at £152,989. 7s. 11d. This amount, however, is subject to revision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending. The traffic receipts show an increase of £2,025, as compared with the corresponding period of last year.

The total expenses of the half-year, including the new offices in New York, repair of cables, &c., as shown by the revenue account, amount to £53,945. 9s. 7d.

One quarterly interim dividend of 12s. 6d. per cent. on the ordinary stock, and of 25s. per cent. on the Preferred Stock, was paid on the 1st May, 1890, absorbing £43,750, and a second quarterly dividend of 15s. per cent. on the ordinary stock, and £1. 10s. per cent. on the Preferred Stock, will be paid on August 1, 1890, amounting to £52,500, leaving a balance of £2,793. 18s. 4d. to be carried forward to the next account.

The Company's repairing steamship "Minia" has been engaged during the past half-year in the repair of the Northern Placentia cable, near Placentia, and of the St. Pierre-Duxbury cable 270 miles from St. Pierre. The vessel was chartered to the Direct United States Cable Company on two occasions for executing repairs, the remuneration for which will be found in the revenue account.

The Company's cables and land lines are in good working order.

Three new offices have been opened in New York, viz.: No. 8, Broadstret, 16, Beaver-street, and 446, Broome-street. The results are encouraging.

No progress has been made since the last report in the litigation between the Anglo-American Telegraph Company and the Paris and New York Telegraph Company, the appeal to the Conseil d'Etat not having come on for hearing.

The agreement between the Société du Cable Transatlantique Français (amalgamated with the Anglo-American Telegraph Company in 1873) and the Submarine Telegraph Company, for the laying, maintenance and work-

Digitized by Google

ing of the cable used by this Company from Brest to Salcombe expired on the 31st March, 1889. The French and English Governments bought the Submarine Telegraph Company's property, with the exception of the cable above referred to, and after long negotiation this Company has purchased the Brest-Salcombe cable from the liquidators of the Submarine Telegraph Company for the sum of £2,000, and by arrangement with the Associated Cable Companies this Company now maintains and works the cable for an agreed annual payment, which forms a charge upon the joint purse payment.

Globe Telegraph and Trust Company (Limited).

The following is the report of the Directors, to be presented to the seventeenth ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Tuesday, July 29, 1890, at 1 p.m.

The net revenue of the Company for the year ended July 18, 1890, after deduction of expenses, amounts to £193,499. 4s. 10d., which, with the balance of £2,054. 10s. 6d., brought forward, make a total of £195,553. 15s. 4d. From this amount there has been distributed the sum of £130,806. 5s. 8d. in interim dividends, leaving an available balance of £64,746. 9s. 8d.

The Directors recommend the payment of a final dividend for the year of 3s. per share on the Preference shares, and of 4s. 3d. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income tax, upon the Preference and 5 per cent. net upon the ordinary shares (against 4⅝ per cent. for the preceding year), and carrying forward a balance of £118. 18s. 6d.

Since the last report 80 shares of the German Norwegian Company have been drawn for amortisation and paid off at par less exchange. It is probable that this cable may be acquired by the German Government within a short period. £890 stock of the Submarine Telegraph Company has been paid off, at 107 per £100 stock; there is still a small return to be made by the liquidators. £200 of the Société Carmichael has been paid off. A further 350 American Cable Company's ($100 fully paid) Shares, with 5 per cent. guarantee of the Western Union Company of New York, have been added to the investments.

The Directors record with much regret the loss of their colleague, the late Sir Daniel Gooch, Bart. They have elected Mr. James Pender in his stead.

In conformity with the Articles of Association William Ford, Esq., and Sir Henry Daniel Gooch, Bart., two of the Directors, retire; but being eligible, offer themselves for re-election.

The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths, and Co.), and Mr. William Griffith, B.A., Barrister-at-Law, also retire at the meeting, and offer themselves for re-election.

Telephone Company of Austria (Limited).

Report to be presented at the seventh ordinary general meeting of the Company, to be held at the offices of the Company, 53, New Broad-street, on Thursday, the 31st July, at 4 p.m.:—

During the year ended 31st March, 1890, there has been expended on capital account a further sum of £10,155. 11s. 10d. The gross receipts from all sources were £16,524. 8s. 8d. After providing for all expenses, including £5,425. 4s. 2d. for debenture interest and dividend on preference and interim dividend of 2½ per cent. on ordinary shares, and £3,032. 0s. 9d. for royalties and taxes to the Austrian Government, there remains a balance of £1,640. 12s. 7d., which, with the amount £3,284. 4s. 6d. brought forward from last year, leaves to the credit of profit and loss account for the current year the sum of £4,924. 17s. 1d.; of this amount it is proposed to place £3,000 to reserve, and to pay a further dividend of 1½ per cent. upon the ordinary shares (making 4 per cent. for the year), leaving £1,047. 2s. 7d. to be carried forward to the next year's accounts.

The Directors are much pleased to again report a continued increase in the number of subscribers to the Company's exchanges, as shown by the following table:—

	No. of subscribers.	Increase over previous 12 months.	Rental.	Increase over previous 12 months.
31st March, 1889	... 2,299	... 263	... 182,550 fl.	... 20,749 fl.
31st March, 1890	... *2,652	... 353	... 210,000 fl.	... 27,450 fl.

* Exclusive of 216 "Extension" telephones which were erected during the year, giving an additional annual rental of fl7,220.

Installations in the towns are still progressing at the usual rate, and, so far as the Board can judge, seem likely to continue to do so. The calls of subscribers now average over 70,000 per week, as against 64,000 last year.

The Government trunk line between Vienna and Prag, which was alluded to in the last report, was successfully completed and opened for the use of the public towards the end of last year. The undertaking has proved a very great success; and, although the outlay to this Company for new switchboards, &c., was considerable, we have reaped the benefit of a fair increase in the number of new subscribers joining the exchange system. The Austrian Government have now in contemplation the connecting up of other towns worked by this Company, on the same terms as the Vienna-Prag Line, *i.e.*, the Government constructs the trunk line and places the Company's exchange subscribers in communication with Vienna, the Company having the indirect benefit of the increase of subscribers.

In relation to the prolongation of the Company's concessions, the Minister of Commerce has fixed the month of October for opening the negotiations, which, your Directors have every hope, will be of a satisfactory nature to the shareholders. Mr. R. Howard Krause, General Manager, visited London in February last, when the details were fully discussed with him, and it is from his statements that the Directors have every confidence in a satisfactory settlement being arrived at.

The cordial and satisfactory relations of the Imperial-Royal Telegraph and Postal authorities and of the municipal bodies with the Company remain unaltered.

The thanks of the shareholders are again due to Dr. Eugen Weissel for his continued valuable services during the past year, and to Mr. Krause for the very satisfactory manner in which he continues to perform his duties as General Manager.

Mr. R. E. Bateman retires by rotation from the Board, but being eligible, offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, but being eligible, offer themselves for re-election.

Edison and Swan United Electric Light Company (Limited).

The following is the seventh annual report of the Directors, to be presented to the shareholders' meeting at the Cannon-street Hotel on Monday, July 28, at 12 noon.

The business of the Company for the year ending June 30, 1890, has resulted in a credit balance of £61,115. 3s. 3d. Of this amount £12,371. 14s. 7d. has been absorbed by the payment of an interim dividend on the "A" shares, at the rate of 7 per cent. per annum, for the first six months of the year. The Directors recommend the payment of the following dividends on the "A" shares, free of income-tax, and to be distributed in accordance with Clause 87 of the Articles of Association:—(*a*) At the rate of 7 per cent. per annum for the half-year ended June 30, 1890 (making 7 per cent. for the year); (*b*) 4 per cent. in completion of payment of arrears of cumulative Preference dividend for the year ended June 30, 1884; (*c*) 4 per cent. in respect of arrears of cumulative Preference dividend for the year ended June 30, 1885; which will absorb £40,649. 19s. 3d.; leaving £8,093. 9s. 5d., which the Directors have carried to the reserve fund, in accordance with Article 89 of Articles of Association.

The Directors have been adding to the buildings and plant at the factory, so as to enable them to manufacture lamps in sufficient numbers to meet the demand which will arise as the supply companies extend their operations in London and other towns.

Mr. Shelford Bidwell, F.R.S., retires from the Board, and offers himself for re-election as a Director. The auditors, Messrs. Welton, Jones, and Co., retire, and are eligible for re-election.

CITY NOTES, &c.

BELL'S ASBESTOS COMPANY.—The Directors have declared an interim dividend of 10s. per share for the half-year ending June 30th last, being at the rate of 20 per cent. per annum. This compares with 12s. 6d. per share, or at the rate of 25 per cent. per annum a year ago.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 18th amounted to £4,174.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors have resolved, after providing for the dividend on the Preference shares, and placing £2,500 to the reserve fund, to recommend a dividend on the ordinary shares at the rate of 8 per cent. per annum, tax free, for the half-year ended June 30, leaving £501 to be carried forward.

EASTERN TELEGRAPH COMPANY.—This Company notify that the coupons on their Five per Cent. Debentures due on the 1st August next will be paid on and after that date at the banking-house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This Company notifies that the coupons on its Six per Cent. Debentures, due on August 1 proximo, will be paid on and after that date at the Consolidated Bank, 52, Threadneedle-street, E.C. Coupons must be left three clear days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—This Company announces the payment by warrants on August 1st next of interest, for the half-year ending July 31st, on their Four per Cent. Mortgage Debentures. The transfer books will be closed from July 27th to August 1st, both days inclusive.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.—The transfer books of this Company will be closed from July 22 to July 28 inclusive, for the purpose of paying a dividend.

MANGANESE BRASS AND BRONZE COMPANY.—Subject to audit, the Directors of this Company propose a further dividend of 13s. per share, making a total of 20s. for the past year, leaving a balance of £4,030 to be carried forward.

MESSRS. P. AND W. M'LELLAN.—The Directors of this Company have declared an interim dividend at the rate of 6 per cent. per annum on the Preference shares, payable on the 11th of August.

STOCK EXCHANGE.—Application has been made to the Committee to appoint a settling day in and to grant a quotation to the Halifax and Bermuda Cable Company (Limited), £120,000 Four and a Half per Cent. First Mortgage Debentures.

UNIVERSAL AUTOMATIC MACHINES COMPANY.—An extraordinary meeting of this Company was held at Cannon-street Hotel on Thursday last, at which the Chairman intimated that the matters in dispute between the Company and Woodhouse and Rawson United had resulted in the arbitrator reducing the claim of that firm from £19,000 to £11,000, the Company also receiving £8,000 as damages, reducing the claim to £3,000. The business of the Company was now in the hands of a receiver, but negotiations had been entered into lately with substantial parties, and he trusted that shortly an effort would be made for taking over the shares in the Company. A resolution was passed empowering the Directors to accept the best terms possible, which terminated the meeting.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY.—The statutory general meeting of this Company was held at Winchester House, Old Broad Street, London, E.C., on the 15th inst.; Sir Douglas Fox presiding. The Chairman said that this was the first statutory meeting of the Company convened for the purpose of complying with the requirements of the Companies Acts, and that there was no special business to transact. It was a great satisfaction to him to be able to state that the number of subscribers for telephones is daily increasing. On December 31, 1889, when the business of the Inter-continental Company was purchased, the total number of subscribers amounted to 1,420, and, according to the last advices from Venezuela, received by cable on June 25, the number of subscribers had increased to 1,681, being 261 subscribers increase in about six months, and there was little doubt that the Company would have 2,000 subscribers by the end of the year. The trunk lines between Caracas and Petare and between Caracas and Antimano are being rebuilt, and it is the intention to extend the former of these lines to Guarenas and Guatire, and the latter to Los Teques. A considerable quantity of material is available at the Company's stores in Venezuela; and this, with further materials already ordered and in process of manufacture will give the facilities necessary for the enlarged business. It is in contemplation to build additional trunk lines between Caracas and La Guayra, and between Valencia and Puerto Cabello, so that there would be seven trunk lines between Caracas and La Guayra, and three between Valencia and Puerto Cabello. With these additional facilities for communication the revenue from these sources should be greatly increased. The Directors had filled up the vacancy on the Board caused by the death of Mr. Francis Bennoch by electing Mr. William Barton Wright. A vote of thanks to the Chairman concluded the proceedings.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended July 15th amounted to £2,879, as compared with £2,553 in the corresponding period of last year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 18, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,208.

WENDIGO COPPER COMPANY.—This Company has been floated during the past week, with a capital of £62,500 in £5 shares, to purchase a large tract of land situate on Isle Royale, Lake Superior, Michigan, U.S.A., amounting in all to over 5,000 acres, on which extensive beds of copper-bearing rocks have been discovered, and to sink mines for the recovery of the metal. The subscription lists opened on Wednesday and closed on Thursday.

CRICKET.—We are able to give the following particulars of two interesting cricket matches which recently took place at Carcavellos between elevens from the Eastern Telegraph Company's cable steamer "Mirror," and from the Company's staff at Carcavellos. The scores were:—First match: Carcavellos, 109; "Mirror," 36 and 56. Second match: Carcavellos, 117; "Mirror," 18 and 81. It will be seen that the Carcavellos staff won both matches easily—the first by an innings and 17 runs, and the second by an innings and 18 runs—partly due, however to the fact that the visitors were out of practice.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 637.—Vol. XXV. FRIDAY, AUGUST 1, 1890. Price Fourpence.

NOTES.

Another historical patent has been demolished, and, shall we say another monopoly has been averted? Last week we did not attempt to sympathise with the owners of a patent who had bought it in ignorance of its potential possibilities; but to-day we give in our Legal Intelligence an abstract of the case which, after being pluckily pushed to the highest appeal, has reduced the connection of Gaulard and Gibbs with the transformer system of distribution, to a mere matter of history; and we sympathise with the inventors. In the spring of 1883 a feeble show was held at the Royal Aquarium, purporting to be an Electrical Exhibition. On the first and last occasion on which we visited this establishment, we saw the exhibit of Gaulard and Gibbs, an "arrangement of induction coils" with movable cores—the first transformers ever made and used for the purpose of running electric lamps. No one heeded the invention. It was thought by several, who should have inquired more carefully, that it was proposed to get more out of the coils than was put into them. The experiment on the Metropolitan Railway in the following year convinced very few. Prof. Forbes gave a guarded opinion as to the efficiency, which was much better than was generally expected. With the exception of some good Exhibition work at Turin, we are not aware that Messrs. Gaulard and Gibbs did anything more until the lighting of the Grosvenor Gallery was being arranged. Lord Crawford then advised that the transformer system should be adopted, and a commencement was made under the supervision of Messrs. Brougham and Mackenzie, the transformers being in series, in accordance with the original intentions of the inventors. In due course Mr. Ferranti appeared on the scene, and it was, we believe, he who found that the parallel system of distribution by transformers must supersede the series system, just as the old "series multiple," or whatever it was called, gave way to supply at constant pressure. We cannot go into the origin of the dispute, nor can we inquire into whether the Messrs. Gaulard and Gibbs are to be credited with the invention of transformers, apart from any legal claim which they have made. The fact remains that they introduced them, although their system was as little regarded at first as was that of the parallel distribution of Mr. Lane Fox.

It was unfortunate that the patentees should have stated in their patent that "the number of secondary generators may be indefinitely multiplied upon the circuit," and that "the primary current . . . . is subject to no other modification than is caused by the resistance of the primary coil." This gave Si Horace Davey an opportunity for saying that "thereby t invention claimed was an impossibility, as it would amount to obtaining perpetual motion." It is, however, a perfectly legitimate statement, and one which had probably been verified by experiment. By "resistance" the inventors presumably meant impedance; and they would as naturally provide higher volts for a greater number of generators as they would do if more arc lamps were added to a series circuit.

The history of this case brings again into prominence the exceedingly unsatisfactory nature of the present method of dealing with disputed patents by the ordinary legal tribunals. The Court of Appeal, although declaring the patent invalid on other grounds, held that it had not been anticipated, in which respect the House of Lords have differed from them. This decision was the more remarkable because the objection of the patentees to some of the alleged anticipations was ultimately reduced to this sole distinction, namely, that either in the drawings or the letterpress of the specification referred to, the induction coil to be used was represented with a core apparently made of a solid piece of iron, whereas their own specification stated that the core was made of iron wires. Most people will agree with the evidence given by Sir William Thomson that the reference to a wire core in the specification of Gaulard and Gibbs was a detail which in 1882 it was quite unnecessary to have mentioned at all, because no one would have thought of using anything else. A great deal of evidence and most elaborate arguments were addressed to this particular point, and much time wasted and expense incurred which would have been quite unnecessary before a tribunal versed in scientific matters. Had the case, however, rested solely upon the question of anticipation and the judgment of the Court of Appeal, the electrical trade would have had to face this strange result, namely, that owing to a mere casual mention in a specification filed in 1882 that a certain induction coil, therein described and since admitted to have no special advantages over other coils, was constructed with a core of iron wires, the whole system of distribution by transformers would have been appropriated by the owners of this patent.

We drew attention in our leading article last week to the distinction which Lord M'Laren made between the sufficiency of description which is necessary to constitute publication, and that which is required for a sound patent. The distinction

Digitized by Google

seemed to us to be noteworthy; but we are surprised to find that *Industries* considers that "the point was merely technical, and it would be a pity for a patent to be destroyed for an infraction of the letter of the law only, while in complete accordance with the spirit of it." Our esteemed contemporary is apparently referring to BRUSH's patent, as that is the only one which has been destroyed. But where was the infraction of the law? It might have contained a thorough and clear account of compound winding, in complete accordance with both spirit and letter of the law; but it was too late. VARLEY had made a prior publication and prior use. On the other hand, Varley's patent may be meant, since it may be suggested that it infringed the letter of the law, but *it* was not destroyed; its soundness was never questioned, except by some of the witnesses. The decision has not touched on the question of sufficiency of description as a qualification for a good patent; but it decides that if Varley's patent had been utterly worthless in this respect it might yet have constituted a prior publication. Our contemporary says that "to the lay mind, at least, it seems fair that a prior publication, in order to invalidate a subsequent patent, must give full instructions to the 'skilled workman,' whoever he may be." But a very ancient example is that of a lock which was in use on a garden gate for a short time before it was patented. It was admittedly impossible for anyone to have learned any details of its construction; but the fact that it had been exhibited in public was sufficient to invalidate the patent.

THE Bakerian lecture on "The Discharge of Electricity through Gases" by Dr. A. SCHUSTER deals with a subject which is too closely allied to chemical science to allow of an extensive use of mathematical treatment, and is in many respects of so speculative a nature that the results arrived at can only be useful so far as they are corroborated by deductions drawn from other parts of physics. The last section, which the author calls the conclusion, and which we reproduce in another column, hardly does justice to the lecture as a whole. The author grudges the ideas of "stress" and "strain," and objects to the term "displacement." The idea of splitting molecules into ions has always appeared to us to be a mere working hypothesis, which is useful enough in supplying a provisional language for the discussion of electrolytic actions. A definite explanation of the dark space round the cathode of a vacuum discharge and of the stratifications and luminous layers is not to be found in this lecture, and there are several statements which are less orthodox than bold; but if from the positions assumed by Dr. SCHUSTER we can get clearer views as to the nature of electricity, we will not urge objections to theories of its atomic constitution.

A GREAT feature was made by the Standard Screw Gauge Committee of the British Association in their final report, of the fact that the system which they suggested was practically identical with that of the screws in use in the Swiss watch trade, and a concession was made to those countries which use the metric system in defining the gauge in millimetres. The B. A. thread would probably have never been heard of again had not the Telegraph Department of the Post Office taken it up. It is being grudgingly adopted in the electrical trades; but none of the watchmaking firms of the Watch Trades Section of the London Chamber of Commerce had ever heard of it, and evinced no interest in it when it was brought to their notice. A very simple but non-geometrical, and therefore arbitrary, system has been recommended for screws between 0·5mm. and 10mm. by the Congress at Frankfort, whose decisions will be found in another column. The pitch is not far different from that of the B. A. screws of corresponding diameter as given in Mr. KEMPE'S Pocket Book, and the second place of decimals for small screws is avoided. We have no details of the system which has been adopted for heavy engineering; but we doubt whether it should go down as far as 5mm., since the WHITWORTH thread is found to be too coarse for screws of less than ¼in. diameter.

IN the account of the electric lighting at Bath, in our issue of June 27, it was stated that the charge made to private consumers is 6s. per annum for each 10 candle-power lamp, the consumer being free to burn his lamps as many hours as he pleases. A correspondent writes to point out that this appears to be an extraordinary charge. Taking the hours from sunset to 11 o'clock at 1,800, a ten-candle lamp, at 3½ watts per candle, gives 63,000 watt hours per annum, which works out at 1·143d. per unit. We have made inquiries, and find that our statement was quite correct; but our correspondent has not noticed that the charge is made upon every lamp fitted. In all residential houses, and in many other cases, only a small proportion of the lamps are lit at once. No electric supply company in London could meet the demand if every lamp were turned on simultaneously; nor would the gas works fare better. Even if the consumers at Bath get a good six shillings worth during the first year, the fact that they have to pay for the lamp renewals will probably check any reckless waste in the future. If we remember right, it was stated before Major MARINDIN that one hour per night per lamp fitted, might be taken as the average duration of lighting. This would make about one-fifth of the number of watt hours reckoned by our correspondent; and would bring the rate per unit up to nearly 5¾d. Even with coal at 14s. Mr. MASSINGHAM will probably find that he had better turn his attention to the question of meters; but, on the other hand, he has probably gone into this question with reliable data, and in a much more careful manner than either our correspondent or we have done.

AT this time of the year a good deal of our space is occupied at the end of the paper with reports of companies' meetings. As different companies draw up their accounts in different ways, they cannot well be compared; but now that sound business is being done it is interesting to analyse the balance-sheets as far as the details will permit. The share capital of the Edison-Swan United Company is close on half a million, and the value of the patents, goodwill, and development is practically one-half of this. Messrs. CROMPTON and Co.'s patents and goodwill are valued at 20 per cent. of their share capital, including debentures, &c. The former Company appear to set the depreciation of their plant at 8·8 per cent., while the latter includes stock-in-trade,

Digitized by Google

and does not give a separate value of the plant; the depreciation on the whole comes to only 2½ per cent. New stock would naturally not suffer depreciation during the current year. The reserve fund of the Edison and Swan Company is 7½ per cent. of their net balance, while that of Crompton and Co. is 12 per cent., and this includes doubtful debts, contingencies, &c. The proportion of net to gross profit is 51½ per cent. in the lamp-making company, while that of the dynamo maker is 41 per cent., but the net profit in both cases includes dividends on external investments. The Directors' and auditors' fees are only 10 per cent. of the earnings of the Edison and Swan Company; these are not given separately in Crompton and Company's statement; but we observe on the other hand, two suspense accounts for new patents and experimental work, which can thus be kept separate from the manufacturing and trading accounts. One cannot expect such companies to discriminate between the value of their patents and that of their goodwill; but we should like to have seen a writing off from the £238,053 of the Edison and Swan patents, instead of an addition of some £2,400.

THE success of the Mining and Metallurgical Exhibition, which was opened at the Crystal Palace on Monday last, is much to be desired on grounds quite apart from those upon which the promoters have built their hopes. So large a population as these islands shelter who are connected with mining industry and metal working is pretty sure to supply a fair contingent of visitors to an Exhibition of such unique and striking interest. But to the public generally, and the investing public in particular, it ought to be useful, not merely as evidence of the mineral wealth that lies buried in the bowels of the earth, but as proof of the enormous difficulties and risks attending the bringing of it to the surface and converting it into a marketable commodity. The hazards of mining, at all events for the nobler metals, have given to it a speculative character from which it will never wholly dissociate itself; but if anything could help to put it on a respectable footing this Exhibition ought to do it—not, however, by raising expectations unduly, but by bringing them down to the level of hard facts. A visit to the shed where the machinery employed in mining industries is at work, ought to disabuse the simplest mind of the notion that the precious ores are anywhere to be had for the mere digging.

ONE of the many excellent suggestions which have been made by the Electrical Trades Section of the London Chamber of Commerce, but one which they found themselves unable to act upon, was the amendment of the clause in the Metropolitan Building Act which limits the size of a building without party walls to 216,000 cubic feet. The London County Council have sought, before a Select Committee of the House of Lords, to introduce an amendment, by which the area may be increased to 450,000 cubic feet. The Corporation of London opposed the amendment on the ground that there would be increased danger from fire. Captain SHAW gave evidence on Wednesday last, and it was decided yesterday to allow 250,000 cubic feet, subject to the consent of the architect of the County Council. A letter from Mr. SLATER to Mr. CROMPTON appeared in our columns on February 7th last.

IT is to be hoped that the report of the Electric Light Committee of the St. Pancras Vestry, of which we give a brief abstract in another column, will be adopted. The action of the first Local Authority that has decided to provide its own electric supply will be watched with interest.

THERE are several points in the remarkable cable accident case recently tried in New York on which further information would be valuable. It is not easy to imagine how the screw of a steamer could become entangled with a cable unless the latter were suspended, and that twelve cables could be chopped up one after the other in this manner by one vessel would be incredible but for the assurance that it had occurred. One would like to know also why the steamer, after breaking, say, half-a-dozen cables, did not take some trouble to clear the remainder, and whether the cables are not marked on the charts of the harbour to enable ships to avoid their locality as far as possible. Then the Judge appears to be under the impression that a submarine cable should be trenched in the ocean bed like a subterrancan land line; and it would be interesting to have his views as to how this could be accomplished. As to the legal aspects of so curious a case one hesitates to express any opinion; but surely, cables laid with the necessary authority have as much right resting on the bottom, whether it be soft or hard, as vessels have in the water; and why the owners of the steamship in question should have been awarded damages it is difficult to see.

Bristol.—The Electric Light Committee of this town have visited Chelmsford and the Kensington and Knightsbridge station.

Telephone Line from Stuttgart to Heilbronn.—This line is being pushed on, and is expected to be in operation within four weeks.

Fire at the Western Union Telegraph Office.—*The Electric Age* gravely offers the suggestion that the Company should have a duplicate plant.

Telephone Operators.—The wages of the lady operators of the National Telephone Company have, according to a letter in the *Financial News*, been raised from 11s. to 12s. per week.

Personal.—The Hon. A. B. Coffin, of the Massachusetts Gas and Electric Light Commission, is now on a European tour. It is his intention to visit the principal gas and electric plants in this country and France.

Telephone in Italy.—The Societa Telefonica Lombarda has had to build an iron structure, 66ft. high, in the Piazetta S. Lepoliro, Mailaud, owing to the householders having declined to allow poles to be put on their houses.

Sofia.—It is intended to light the town of Sofia, Bulgaria, with electricity, using the water of the Boyena as the origin of power. The cost of initial establishment is estimated at £20,000 to £24,000. Tenders will be invited in August.

A Fine Climate.—The *Financial News* says that they are asked to believe that out in Nevada telegraph poles in low places, where water stands in winter, have taken root and are covered with foliage. The poles are cottonwood, and were planted with the bark on them.

Electric Railway at Neustadt.—The Neustadt Cement Works, which already are lighted by electricity, have now built an extension of the railway from the terminus to their works, a distance of 1,700 metres. An electric locomotive draws three trucks each carrying three tons, the journey being performed in ten minutes.

"The Electrician" Annual Dinner.—The seventh annual dinner of the staff of *The Electrician* took place on Monday

Digitized by Google

last at the Mitre, Hampton Court. The weather was fine, and a very enjoyable day was spent. An excellent dinner was provided for the 62 members of the staff and visitors, and this was followed by a short programme of toasts and music.

Telephone in the West Riding of Yorkshire.—It is proposed to establish telephone exchanges throughout the West Riding (in the first instance) at greatly reduced rates—probably one-third of the National Telephone Company's charges. The Council of the Keighley Chamber of Commerce have decided to give their heartiest support to the scheme.

Owens College, Manchester.—A special course in electrical technology has been arranged to commence at this College on October 7th. That the instruction will be of a most complete kind may be gathered from the fact that a dynamo house has been built containing two direct and two alternate current dynamos to be used for experimental purposes.

Fulham.—At a meeting of the Vestry the Lighting Committee reported that they had received notices on behalf of the House-to-House Electric Supply Company, and the Stamford Hill, Tottenham, and Edmonton Electric Light and Power Supply, stating their intention to apply to the Board of Trade in due course for electric lighting Provisional Orders.

Extension of St. James's and Pall Mall Company.—At the annual dinner of the St. James's Vestry Mr. Latimer Clarke said that, in addition to the present station of the St. James's and Pall Mall Electric Light Company in Mason's-yard, it was proposed to establish another in the northern part of the parish, from which, in addition to the electric light, arrangements would be made for the supply of a considerable amount of electric power for the purpose of driving machinery.

Barnsley.—At a meeting of the burgesses of the South-West Ward last week, it was unanimously resolved that, having regard to the arbitrary and discourteous manner in which the Gas Company have treated the Town Council, and gas consumers generally, the Corporation should at once put down an installation for the supply of electricity. At a meeting of the Town Council on the 29th ult. it was decided by 15 votes to 5 to proceed with the electric lighting of the inner portion of the town under their Provisional Order.

The Ferranti System in France.—Besides the supply stations at Nancy, Troyes, and Havre, the Société Nationale d'Electricité, which is working M. Ferranti's system in France, has in hand work at Rethel, Vierzon, Nimes, Sens, and Amiens. They are in negotiation with the Municipal Council of Paris for a concession for lighting a portion of the left bank of the Seine, including part of the Fifth Arrondissement and the quartier of Sorbonne. The Company offered a deposit of £4,000, but the Council demand £6,000, and decline to return it.

Gas Companies and Electric Supply.—The President of the Conference of North British Gas Managers in his address at the meeting of the Association at Perth on the 24th ult., after a passing allusion to the experiments made in Greenock of supplying a section of that town with electric light, said it was evident that the electric light could not be supplied at anything like the cost of gas. Gas was the light of all classes of consumers; but the electric light, from its excessive cost, could only be the luxury of the rich. Where gas was sold as cheaply as it was in most towns, there was no risk of the general adoption of the electric light. In his opinion the supply of electricity should be left in the hands of those companies who specially undertook such work, and gas companies should no more trouble themselves with it than they would with the supply of oil to those who prefer to burn this illuminant instead of gas, oil being a much more active competitor than electricity.

Electro-Technical Laboratory at Magdeburg.—At the instance of a number of Magdeburg manufacturers, an electro-technical experimental station is, according to *Nature*, about to be founded in that town, to afford to companies or private persons opportunity of experimenting as to the practicability and cost of various electrical arrangements, and of testing machines, apparatus, &c. The station will be arranged on the pattern of one already in existence at Munich, but expanded in several directions. Dr. M. Krieg, editor of the *Electrotechnical Echo*, will be at its head. Among other matters which will come under its consideration are the examination of arrangements for illumination, transmission of force, and metallurgical purposes, determination of the luminous power of arc and glow lamps, and of constants, such as intensity and tension of current, testing of carbon rods, of measuring instruments, accumulators, primary batteries, &c., examination of conducting and insulating materials, lightning conductors, private telephone arrangements, and so on. Youths devoting themselves to electro-technical work will have opportunities of gaining thorough practical knowledge in the place.

Damage to Cables by a Screw Steamer.—The recent decision by the United States District Court in counter suits brought by the Western Union Telegraph Company and the Inman Line Steamship Company is of interest to submarine cable companies. The propeller of a steamship became entangled with some of the cables landing at Jersey City; twelve cables were broken, and the vessel had to be dry-docked to clear away the remnants from the propeller. The steamship company claimed $2,000 damages and the Western Union over $60,000, and the former won the day. On behalf of the telegraph company it was claimed that they had exclusive right to the silt or mud as a resting place for the cables, and that the propeller caught up the cables from the mud in which they were imbedded. Judge Brown decided that no such right is upheld in the Act of Congress, which permits cables to "go under water, but not so as to obstruct navigation." Nothing in the Act, he asserts, gives any absolute right to lay cables in all cases on the very top even of solid bottom. "There can be no practical difficulty in sinking cables so deeply as not to possibly interfere with the movements of vessels in any and all emergencies of navigation. The use by steamers in the harbour of the undefined margin of silt or mud between the solid bottom and clear water is necessary."

Standard Screw Thread.—The Congress for the standardising of the screws employed in fine machinery (*la mécanique de précision*) took place at Frankfort on June 2nd and 3rd. Several authorities of the German Government, the German Society of Engineers, the Electro-technical Society, and a great number of local associations and institutions were represented. The object, says the *Revue Internationale*, was to arrive at an understanding by which the inconveniences arising from the innumerable kinds and different forms of screws (more than 800) actually employed in fine machinery might be stopped. It will be remembered that the German engineers (that is to say, the representatives of heavy engineering) had previously found themselves faced by the same difficulty, and had established a standard scale down to bolts and screws of 5 millimetres diameter. The Congress adopted the following decisions: 1. The resolutions of the Congress to apply to screws up to 10 millimetres diameter. 2. The thread to have sharp edges (*à arête vive*). 3. The angle of the thread should be 58° 8. 4. The height should be equal to the depth. 5. Only one pitch will be used for each diameter. 6. The usual dimensions will be the following for holding screws (*les vis d'assemblage*):—

Dia. mm.	Pitch mm.	Dia. mm.	Pitch mm.
0·5	0·15	4·0	0·7
0·6	0·15	4·5	0·8
0·8	0·2	5·0	0·8
1·0	0·2	5·5	0·9
1·2	0·2	6·0	1·0
1·4	0·3	7·0	1·1
1·7	0·3	8·0	1·2
2·0	0·4	9·0	1·3
2·3	0·4	10·0	1·4
2·6	0·5		
3·0	0·5		
3·5	0·6		

From 5 to 10 millimetres diameter there will be two scales, one for fine machinery and that of the Society of Engineers. The Congress hopes that the latter will consent to put back the lower limit of their scale to 10 millimetres; if so, the dimensions of the threads will be reduced to one type for each diameter of screw.

MAGNETISM IN IRON AND OTHER METALS.*—XXV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 309.*)

§ 94. **Later Experiments using the Isthmus Method.**—In subsequent experiments† the induction in iron was forced to much higher values by using a larger electro-magnet and by turning down the neck of the bobbin. The extent to which concentration of induction in the neck may be carried depends on the sectional area of the neck in comparison with that of the pole from which the lines converge. In the following experiment the section of the neck was reduced until it was finally only $\frac{1}{1500}$ that of either pole. The magnet—an exceptionally powerful one, belonging to the Physical Laboratory of Edinburgh University—was excited with 64,000 ampere-turns, and its force was concentrated from poles about 10 cms. square upon a neck or isthmus 2·66 mm. in diameter and 3·5 mm. long. Fig. 67 is a full-size sketch of the poles with the bobbin in its place after its neck had been reduced to the smallest diameter. The dimensions are entered in millimetres. The bobbin *c* was the same bobbin of annealed Lowmoor

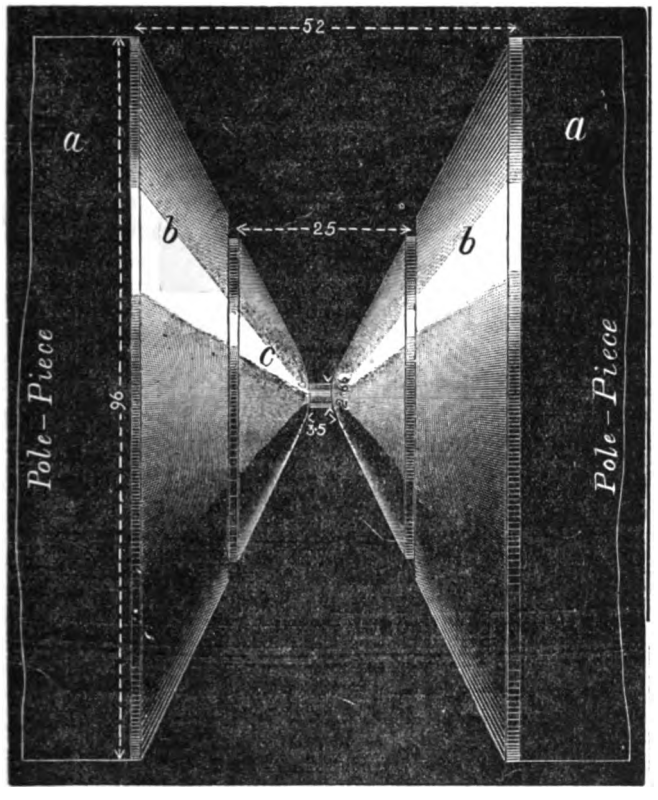

FIG. 67.

wrought iron as had been used in the earlier experiments, a pair of separate conical pieces *bb* being interposed to connect its ends with the pole-faces *aa*. With each reduction in the size of the neck a higher value of B was reached; finally when its diameter was 0·266 mm. the induction B was 45,350, and the force in the space immediately surrounding the neck was 24,500. From other experiments we may infer that this was, as nearly as possible, equal to the actual magnetic force within the metal: hence the result may be written thus:—

H	B	I	μ
24,500	45,350	1,660	1·85

No attempt was made to reduce the neck further, and this is the highest induction that has hitherto been recorded in any experiment. There is no reason to doubt, however, that higher values of H and of B might be obtained by using an electro-magnet of greater size and power.

§ 95. **Theory of the Isthmus Method: Form of Cone to give Maximum Concentration.***—Consider an imaginary section through the middle of the neck, at right angles to the axis of the bobbin. It is clear that there is no discontinuity between the magnetic force, at points in this plane, inside and outside the metal, for there is no free magnetism on the surface of the neck at the middle of its length. We have to consider the conditions which will make the magnetic force as nearly uniform as possible over this medial section in order that the force just outside the neck, which we are able to measure, may be fairly representative of the force inside the neck itself.

The magnetic force in the space between the pole-pieces is made up of two parts: (1) the electro-magnetic force directly produced by the current in the magnet coils; and (2) the force due to free magnetism distributed for the most part over the pole-faces. The first of these forms a comparatively small part of the whole; and its value is sensibly uniform at such small distances from the axis as those with which we are now concerned. In considering the conditions which will secure the greatest strength or the greatest uniformity in the field at the neck, we need only deal with that part of the force which is produced by free magnetism.

The free magnetism of the pole-faces may be treated as made up of a series of co-axial circular rings in planes normal to the axis of the bobbin. Calling M the whole free magnetism of one of these rings (Fig. 68) and r its radius, the magnetic force F due to it at a point in the axis at a distance x from the plane of the ring is $\frac{Mx}{l^3}$ where $l = \sqrt{r^2 + x^2}$. This force will be a maximum when $\frac{dF}{dx} = 0$, that is, when

$$\frac{1}{l^3} - \frac{3x^2}{l^5} = 0,$$

which occurs when $x = \frac{r}{\sqrt{2}}$; $\tan\theta = \sqrt{2}$; $\theta = 54° 44'$ Hence a series of co-axial rings will be most advantageously disposed

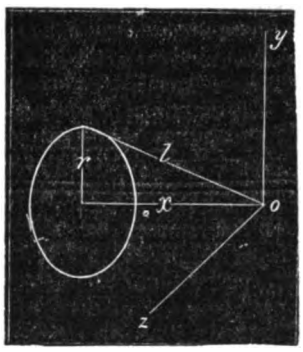

FIG. 68.

for producing force at a point on the axis if they lie on a cone having its vertex at the point in question, with a semi-vertical angle of 54° 44'.

The greatest force will be produced when the pole-pieces are themselves saturated, so that I reaches its limiting value in all parts of the metal. In that case the distribution of density from ring to ring is uniform. The surface density of free magnetism at any point of a sloping pole-face is $I \sin\theta$, where θ is the slope of the face to the axis of magnetisation. The whole quantity in each ring is I multiplied by the area of the ring projected upon a plane normal to the axis—a quantity which is independent of the slope of the cone. We have, therefore, the same series of attracting rings to deal with, whatever be the slope of the convergent faces, and whether that slope be uniform or not. Given, then, a certain diameter

* All rights are reserved.

† Ewing and Low, *Phil. Trans.* vol. 180, 1889, A, p. 221; *Rep.* Brit. Assoc., 1887, p. 586.

* Parts of this and the succeeding paragraphs are taken from the Paper cited (*Phil. Trans.* 1889, A, p. 221).

Digitized by Google

for the neck of the bobbin to be magnetised, the greatest magnetic force will be produced at the middle of the axis of the neck, when the pole-pieces are saturated and when we make the expanding ends and pole-faces in the form of cones, with a semi-angle of 54° 44′, and with their vertices at the middle of the neck.

This determines what may be called the cones of maximum concentrative power. In practice cones intended to produce as great a concentration as possible should have a somewhat greater semi-angle—say 60° or so—because of the defective saturation of the pole-pieces.

§ 96. Greatest Magnetising Force producible by Means of Cones.—With a cone of any semi-angle θ, magnetised to a uniform intensity I_0, the surface density of free magnetism is $I_0 \sin\theta$, and the force at the vertex due to a ring at an axial distance x, of radius r, and of length dl, measured along the slope, is

$$2\pi r\,dl.\,I_0 \sin\theta.\frac{x}{l^2}, \text{ or } 2\pi I_0 \sin^2\theta\cos\theta\frac{dr}{r}.$$

The whole force at the vertex is

$$2\pi \sin^2\theta\cos\theta\int_a^b \frac{I_0\,dr}{r},$$

a being the radius of the neck on which the cone converges, and b the radius of the base to which it spreads.

Hence (treating I_0 as uniform), with a pair of truncated cones, joined by a neck at the middle of which they have their common vertex, the whole force there is

$$F = 4\pi I_0 \sin^2\theta\cos\theta\log_\epsilon\frac{b}{a},$$

which, for convenience of calculation, may be written

$$F = 28{\cdot}935\, I_0 \sin^2\theta\cos\theta\log_{10}\frac{b}{a}.$$

Applying this to the cones of maximum concentrative power (§ 95), in which $\sin\theta = \sqrt{\frac{2}{3}}$ and $\cos\theta = \sqrt{\frac{1}{3}}$.

$$F_{max.} = 11{\cdot}137\, I_0 \log_{10}\frac{b}{a},$$

and the greatest value of the force will be obtained when I_0 has the saturation value (of say 1,700 C.-G.-S. units for soft wrought iron), in which case

$$F_{max.} = 18930\,\log_{10}\frac{b}{a},$$

an expression which measures the greatest possible force which the isthmus method of magnetisation can apply at a point in the axis of the bobbin (over and above the small force which is directly produced by the magnet coils). It is not practicable to produce quite so large a force, because the magnet poles cannot be fully saturated.

§ 97. Form of Cone to give most Uniform Field.—The cone of maximum concentrative power is not the form best suited for producing a uniform magnetic force throughout the neck. It makes the field rather stronger at places near the axis than on the axis itself. To make the field as nearly uniform as possible in and close to the neck we must slope the cone at such an angle that $\frac{d^2F}{dx^2} = 0$, a condition which secures that $\frac{d^2F}{dy^2}$ and $\frac{d^2F}{dz^2}$ shall also be zero. This condition is satisfied when

$$\frac{9x}{l^5} - \frac{15\,x^3}{l^7} = 0,$$

which makes $x = r\sqrt{\frac{3}{2}}$; $\tan\theta = \sqrt{\frac{2}{3}}$; $\theta = 39° 14'$.

In other words, the best approximation to a uniform field (the pole-pieces being saturated) is reached when the pole-faces are cones converging upon the middle of the neck, with a semi-vertical angle of 39° 14′. When the cones have this form, and he neck is very narrow in comparison with the base, the field is so nearly uniform that the magnetic force in a narrow ring of space close to the neck may be taken to represent, without sensible error, the force within the neck itself, and there is no practical variation of the force in the neck from end to end, or from side to centre.

With cones of this form the concentration of force upon the neck is less than in the former case. Using the same notation as before the force is

$$15{,}240\,\log_{10}\frac{b}{a},$$

in the event of the poles being of wrought iron and fully saturated.

The difference between the two cases is illustrated by Figs. 69 and 70, where curves are drawn to show the force exerted at

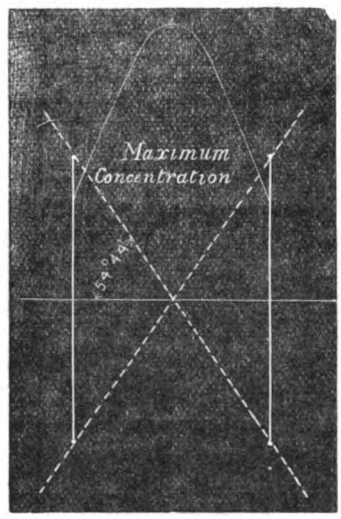

FIG. 69.

various points on the axis by a single pair of rings, forming parts of conical pole-faces which have a common vertex. In Fig. 69 the rings are parts of cones of maximum concentration; in Fig. 70 they are parts of cones shaped to produce the best

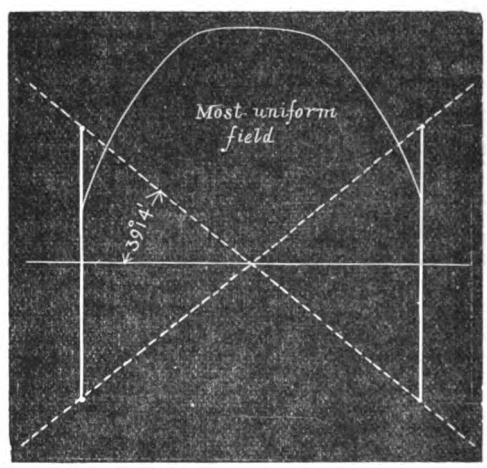

FIG. 70.

possible approximation to a uniform field. The rings are taken equal in both cases, so that the height to which the curves rise in the middle will serve for comparison of the forces; the flatness of the curve in Fig. 69 shows the superiority of that form of cone in respect to uniformity of field. With actual conical pole-pieces, the force produced in the neck is, of course, made up of the sum of the forces due to pairs of rings like these distributed over the whole conical surface.

(To be continued.)

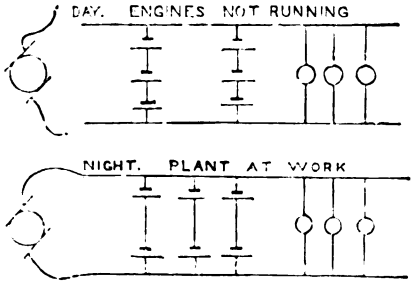
THE LIGHTING OF LONDON THEATRES BY ELECTRICITY.

BY ED. C. DE SEGUNDO, A.M.I.C.E.

From the comprehensive nature of this title the reader might be led to expect a more complete account of this subject than is contained in the following lines. I must, therefore, commence with an apology for leaving entirely out of account the historical side of the question, inasmuch as to do justice to this subject from an historical point of view would entail the double disadvantage of taking up a considerable amount of space, and of giving rise to possible distinctions as to whom honour is due as the pioneer of electric lighting in theatres in London and so forth. I need, for similar reasons, offer no further apology for not introducing any remarks of a critical nature, this article being intended to be purely of a descriptive character.

The majority of theatres in London which are lighted by electricity are supplied by suitable plant erected on the premises; and as only those installations which possess some features of novelty need be described, I propose to enter briefly into the details of the plant erected at the Lyric Theatre, Mr. D'Oyly Carte's new theatre, the Court Theatre, and Covent Garden Theatre; and to append a table giving the types of installations in use at, or the manner in which electrical energy is supplied to, the chief theatres now lighted by electricity in London.

Through the kindness of Messrs. J. B. Verity and Sons, of King-street, Covent-garden, I have had an opportunity of examining the plans of the installation now being erected to supply Mr. D'Oyly Carte's new theatre. The plant consists of three Marshall boilers of the locomotive under-flue type, 16ft. long, supplying steam at 140 pounds per square inch to three



Willans double-tandem compound high-speed engines, each coupled direct to a Siemens dynamo, capable of giving 650 amperes at 110 volts. The boilers are fed by a duplicate set of two cylinder steam force pumps, arranged to draw either from a feed water-heater through which a portion of the exhaust from the engine passes, or to supply direct from a tank filled by the water main. Two other heaters, also operated by the exhaust from the engines, supply the hot water for heating the building. In regard to this latter question, it is intended to supplement the heating of the auditorium by means of a fan which will draw air from the room in which the resistances are placed and discharging into the house, while a 2½ horse-power motor will actuate a fan in the dome for ventilating purposes.

The engines are each of 135 horse-power, and the steam from the boilers passes first through a separator placed by the side of the engine, to which is attached a water gauge and trap whereby any accumulation of water is expelled. Enough storage plant in the shape of two sets of 31-L.E.P.S. cells, each consisting of 55 in series, is provided for all day work, such as rehearsals, cleaning, &c.; and a special feature in the arrangement is an ingeniously devised switch, by means of one turn of which the two sets are coupled up in three sets in parallel with the lamp circuit during the run at night, thus acting as equalisers and also receiving a charge for the next day's work, the changes being diagrammatically represented above :—

In regard to the installation in the theatre the following points may be mentioned. The switchboard is at some elevation from the stage, so that the operator in no way interferes with stage work, and the various apparatus are out of reach of an accidental injury. The necessary resistances are collected in a room below the stage, and are in the form of straight runs of platinoid wire, about 100 feet being allowed for every 60 amperes of current, the electromotive force being reducible from 100 to 50 volts. These resistances are operated from the switchboard gallery by means of cords. Unfortunately, the theatre is not in a sufficiently advanced state to enable any judgment of the internal fittings to be made; but these, there can be no doubt, will be of the newest and most tasteful design, as no expense is being spared to ensure the complete success of the lighting arrangements. Messrs. Verity and Sons are introducing some new points in battens; but these are not yet sufficiently worked out, and any publication of such details would naturally be premature.

The Lyric Theatre.—This installation is, I believe, originally due to M. Sechehaye, a Swiss engineer, and is certainly a most complete installation for theatrical purposes. Mr. Henry Lyon, who has been in charge from almost the time the theatre opened, has kept a most complete and detailed record of the performance of the plant day by day, and has been good enough to put me in possession of very complete details not only of technical but of commercial matters. The importance of the commercial side of the question is, of course, great, and the value of the figures given me by Mr. Henry Lyon is manifest, inasmuch as they are taken from accounts actually paid. Before quoting these figures a description of the plant would be interesting, as it constitutes a unique system of generation and distribution.

The power is supplied by two 16 horse-power nominal Stockport gas engines, each working up to about 23 brake horse-power, and each belted to a Statter dynamo. The engines, though somewhat wasteful in gas consumption (32 cubic feet per indicated horse-power per hour) have given great satisfaction. Mr. Lyon reports no serious break-down, although they run from 18 to 20 hours a-day regularly. The dynamos are coupled either singly or in parallel to one or more sets of cells as occasion may require. The battery plant consists of 424 31-L. E.P.S. cells arranged in eight parallels of 53 in series. The charge and discharge are controlled by a very complete and conveniently-arranged switchboard, the large lever-switch controlling the end cells of each battery being designed to avoid the sparking that would ensue in switching a parallel of end cells in or out of charge or discharge, by short-circuiting the cells, as the switch passes from one contact block to the other, through a resistance. The whole of the lights in the house are arranged on 13 main circuits, each controlled by a single pole brush switch on the lead and return. The various circuits are so arranged as to admit of the most complete and easy control of the lighting of the theatre under the various circumstances. The stage switchboard is placed at some elevation from the stage, the operator being thus perfectly free and unmolested—an advantage both for the management and for the operator.

The arrangements on the stage are of the most complete nature. I do not remember any theatre I have seen in which the light from the battens can be varied both in intensity and in colour to so great an extent and with such ease. No limelights are used, the necessary effects being produced by portable arc lamps. Mr. Lyon gave a practical demonstration of the above assertions, and kindly went into the detail of his novel system of liquid resistance, which he has protected, and which by a very simple device reduces to a minimum the noise of the explosion of the collected gas on the plates ignited by the inevitable spark when the lamps are finally extinguished. It is perhaps worthy of mention that there is not a single gas-jet anywhere on or near the stage; and the 21 months' run without any breakdown serious enough to cause an extinction or even a diminution of the intensity of the lights, from 424 storage cells charged by gas-engine power, reflects great credit on Mr. Lyon's system of supervision and arrangement. I may just mention, without comment, that this installation, as designed by M. Sechehaye, cost £19,000.

THE LONDON AND PARIS TELEPHONE CABLE.

Telephonic communication between London and Paris is now merely awaiting the consent of the French Government. Mr. Preece stated at the Newcastle meeting of the British Association that experiments had been made to ascertain under what circumstances such communication was possible; and in February, 1887, he communicated to the Royal Society a Paper in which it was stated that, taking the resistance of a conductor in ohms, and its capacity in microfarads, telephonic communication is good, when the product of these is 5,000; when it is 10,000 talking is just possible, and the limit is reached at 15,000, when no articulation is audible. Experiments have been made with telephones on the cables between Dover and Calais, between Holyhead and Dublin, between South Wales and Wexford; and from the results of these, the officials of the Post Office are perfectly satisfied that they can build a line between the capitals of the two countries through which telephonic communication will be not only possible, but highly satisfactory.

The present cable between Dover and Calais is quite unsuitable for the purpose, both on account of its high resistance and its capacity. The requisite details of the new cable and the land lines have been worked out, and the results of the calculations have been compared with the tests recently made upon a line from Baldock in Hertfordshire, through London to Worcester. In this experiment, which was conducted with the view of determining the constants of the proposed line to Paris, two copper wires were employed, and no less than 27 miles of the circuit was through the underground system of the postal telegraphs in London. The communication through this line by telephone was very good, and confirmed in a very satisfactory manner the calculations which have been made. The telegraphic communication between London and Paris has increased very considerably during the past few years; and as it is necessary to make some extensions, it has been considered that the new line should be one through which telephony could be carried on.

The land line will consist of four copper wires, and M. Jules Roche has asked the Chamber of Deputies for a grant of £16,000. A Bill has been introduced to create a supplementary credit for this amount at the Ministry of Commerce. This represents the share of the French Government in the cost. A further outlay of £12,000 will probably be required. The route of the new cable will be between Sangatte, near Calais, and Folkestone.

As soon as the Bill has passed the Chamber operations will be commenced; and, as the French Government are fully alive both to the importance and to the practicability of the matter, it is not likely that any obstacles will arise, and it may be expected that the line will be ready before the end of the year.

THE WORKING EFFICIENCY OF SECONDARY CELLS.*

By W. E. Ayrton, C. G. Lamb, E. W. Smith, and M. W. Woods, Associates.

(Continued from page 321.)

We therefore adjusted the automatic interruptor to stop the discharge when the potential difference per cell was 1·8 volts, and the immediate result of this was to bring the time of charging up to 12½ hours, and to bring up the time of discharging to 10½ hours. After continuing the charging and discharging continuously day and night for 13 days, the cells reached a perfectly steady state. Curve 8 shows the time curve of potential difference per cell in the discharges finished in the early morning of June 19th, recommenced in the night of June 19th, and again commenced late on June 20th, all the three discharges being so precisely similar that they can be represented by one curve; and, similarly, curve 9 shows the intermediate charging curves on June 18th, 19th, and 20th, which were also exactly the same. The times of the three discharges and of the three charges were, respectively, in hours and minutes—

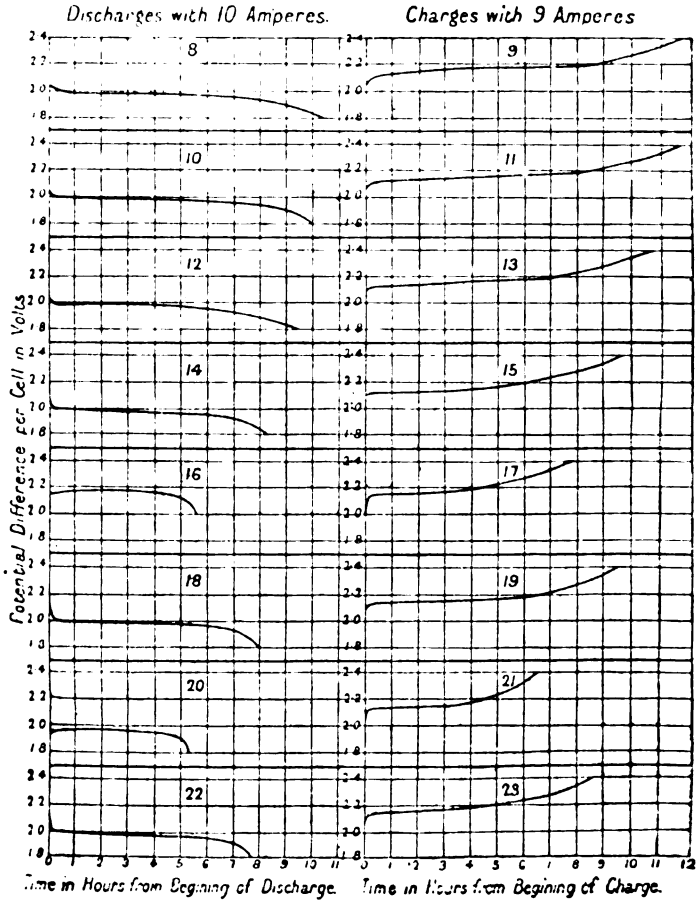
Times of Successive	
Discharges.	Charges.
10 h. 10 m.	11 h. 38 m.
10 h. 10 m.	11 h. 37 m.
10 h. 11 m.	11 h. 37 m.

showing to what an absolutely definite state cells arrive after a definite cycle of charge and discharge between fixed limits has been repeated continuously without interruption for some weeks.

Integrating these curves, we find—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell	Quantity.	Energy.
101·9	201·7	104·5	230·7	97·2	87·4

The numbers contained in this last table may probably be considered as giving the steady working values for this size and type of cell. 230·7 watt-hours are equivalent to 612,200 foot-lbs., and as the positive and negative plates of one cell weigh 28lb. 10oz., the *working* storage capacity is 21,380 foot-lbs. per lb. of plate.



Discharges with 10 Amperes.
Charges with 9 Amperes
Potential Difference per Cell in Volts
Time in Hours from Beginning of Discharge.
Time in Hours from Beginning of Charge.

VII.—*Effect of Rest.*

We next tried the effect produced on the capacity and efficiency of accumulators by prolonged rests. The five cells used in the experiments stood on porcelain insulators containing resin-oil; and as the insulators, which were specially made for the Central Institution, were taller than those commonly employed to support accumulators, and as all connecting wires were removed from the cells while they were allowed to rest, it is certain that any change in the cells must have been caused by internal action, and could not have been due to external leakage.

The cells, having been fully charged on June 22nd, were allowed to rest, insulated as above described, until July 2nd—that is, for 10 days. The first few curves of discharge and charge after the rest showed a considerable diminution in the capacity and efficiency; but after one week's continuous charging day and night, a steady cycle was reached, the following being the times of successive dis-

* Read at the Extraordinary General Meeting of the Institution of Electrical Engineers at Edinburgh, on July 16th, 1890.

charges and charges, the limiting potential differences, as before, being 1·8 and 2·4 volts :—

TIMES OF SUCCESSIVE

Discharges.	Charges.
10 h. 1 m.	11 h. 35 m.
9 h. 59 m.	11 h. 30 m.
9 h. 58 m.	11 h. 32 m.
9 h. 57 m.	11 h. 33 m.

Curves 10 and 11 show the variation of the potential difference per cell ; and on integrating these curves we obtain :—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
100	198	103·8	228·2	96·4	85·8

Rest, then, of an accumulator, although left well insulated and fully charged at the commencement, alters the accumulator so that for the first few charges and discharges after the rest it is a much less valuable instrument than before. A week's continuous charging and discharging day and night, however, removes this effect to a great extent ; the efficiency, however, still remains somewhat lower than before the rest.

Next, the cells were allowed to rest charged for 12 days, until August 1st. The first discharge at the end of the rest gave a quantity efficiency of only 80 per cent., so that 20 per cent. of the charge was lost. After a week's continued charging and discharging between the former limits of volts, the cells regained a steady state, but the time of charge and of discharge is now less than before this second rest. The times after the week's charging and discharging were :—

TIMES OF SUCCESSIVE

Discharges.	Charges.
9 h. 3 m.	10 h. 41 m.
9 h. 2 m.	10 h. 44 m.
9 h. 10 m.	10 h. 51 m.

Curves 12 and 13 show the potential difference curves when the cells had acquired a steady state, and on integrating them we find :—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
91	176·7	96·8	213·2	94·1	82·8

We see, then, that a week's continuous charging and discharging of these cells is unable to compensate for the harm produced by their being left for 12 days fully charged. The two rests of 10 days and 12 days respectively, although followed in each case by a week's continuous charging and discharging, have reduced the discharge ampere-hours by 10 per cent., the discharge watt-hours by 12 per cent., the quantity efficiency by 3 per cent., and the energy efficiency by 5 per cent.

Third Rest.—The cells having been fully charged, a third rest of 16 days took place. On the first discharge, at the normal rate of 10 amperes, the ampere-hours were only 75. After, however, the charging and discharging at the normal rates had been continued for three days and nights, the times of discharging and charging became steady.

TIMES OF SUCCESSIVE

Discharges.	Charges.
8 h. 12 m.	9 h. 28 m.
8 h. 17 m.	9 h. 35 m.
8 h. 19 m.	9 h. 35 m.

and curves 14 and 15 show the working values of the potential difference in discharging and charging. Integrating the curves, we obtain :—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
82·6	161·3	86·2	190·5	95·8	84·7

Fourth Rest.—The cells, having been fully charged, were allowed to rest for 16 days. Curve 16 gives the values of potential difference obtained at the *first discharge*, and curve 17 the values of the potential difference obtained immediately afterwards in charging. Integrating the former curve, and comparing its area with the area of the charge curve 15 obtained just before the rest, we find :—

First discharge after rest.		Last charge before rest.		Percentage efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
56·5	110·5	86·2	190·5	65·5	58

If, however, we compare the result of the first discharge after the rest with the first subsequent charge, shown in curve 17, we find :—

First discharge after rest.		First charge after rest.		Percentage efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
56·5	110·5	71·1	158·3	79·6	69·6

The cells were now continuously, without intermission, charged with the normal current of 9 amperes, and discharged with 10 ; the discharge, as before, being automatically stopped when the potential difference per cell had fallen to 1·8 volts, and the charge when it had risen to 2·4 volts. The following give the successive times in hours and minutes in which the cycles were completed :—

First discharge after rest,			5h. 40m.	First charge,	7h. 54m.
Second	„	„	7h. 6m.	Second „	8h. 30m.
Third	„	„	7h. 31m.	Third „	8h. 51m.
Fourth	„	„	7h. 29m.	Fourth „	8h. 52m.
Fifth	„	„	7h. 43m.	Fifth „	9h. 17m.
Sixth	„	„	8h. 0m.	Sixth „	9h. 24m.
Seventh	„	„	8h. 5m.	Seventh „	9h. 17m.
Eighth	„	„	7h. 57m.	Eighth „	9h. 20m.

From the last three discharges and charges we see that the cells have arrived at a steady state, and curves 18 and 19 show the steady, or working values of the potential difference for these three discharges and charges. Integrating the areas of these two sets of curves, we find :—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
80	156·9	83·8	184·6	95·5	85

Fifth Rest.—The cells were now left charged for a further period of 16 days. Curve 20 gives the values of the potential difference obtained at the first discharge after the rest, and curve 21 the values of the potential difference obtained immediately afterwards in charging. Integrating the areas of these curves, we have :—

First discharge after rest.		Last charge before rest.		Percentage efficiency.	
Ampere-hours.	Watt-hours per cent.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
53·3	104·1	83·8	184·6	63·6	56·4
		First charge after rest.			
		58·5	128·3	91·1	81·1

Continuous charging and discharging with the normal currents between the normal limits of potential difference per cell gave the following times for completing the cycles :—

First discharge after rest,			5h. 20m.	First charge,	6h. 30m.
Second	„	„	6h. 18m.	Second „	7h. 29m.
Third	„	„	6h. 42m.	Third „	7h. 59m.
Fourth	„	„	6h. 54m.	Fourth „	8h. 19m.
Fifth	„	„	7h. 15m.	Fifth „	8h. 20m.
Sixth	„	„	7h. 16m.	Sixth „	8h. 30m.
Seventh	„	„	7h. 23m.	Seventh „	8h. 41m.
Eighth	„	„	7h. 34m.	Eighth „	8h. 44m.
Ninth		„	7h. 40m.	Ninth „	8h. 47m.

7 6	76	149·5	22	8 12	78 3	173·5	23	97·1	86·3

It was concluded from the times of the last three charges and discharges that the cells had acquired a steady state, and curves 22 and 23 show the time fall and the time rise of potential difference. Integrating the areas of these curves, we have :—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
76	149·5	78·3	173·2	97·1	86·3

The above table gives a *resumé* of these results, all the discharges being made with 10 amperes until the potential difference cell to 1·8 volts per cell, and all the charges being made with 9 amperes until the potential difference per cell rose to 2·4 volts. Before each rest the cells were charged until the potential difference per cell was 2·4 volts.

From the preceding table it will be seen that, in spite of the continued charging and discharging at the end of each rest, there is a steady falling off in the quantity capacity from 101·9 ampere-hours at the beginning to 76 ampere-hours at the end, and in the energy capacity from 201·7 watt-hours to 149·5 watt-hours. The quantity and energy efficiencies, 97·1 and 86·3 per cent. respectively, at the end are the same as at the beginning. Comparing the first discharge after each of the 16 days' rest with the last charge before the rest, there appears to be a loss of about 36 per cent. in the ampere-hours, and about 43 per cent. in the watt-hours ; or, since the normal quantity and energy efficiencies for a discharge immediately following a charge are respectively 97 and 87 per cent., it follows that the rest of 16 days causes a loss of about 33 per cent. in the ampere-hours, and about 30 per cent. in the watt-hours, in addition to the losses that normally occur on a charging immediately followed by a discharging.

From all that precedes, it follows that the previous history of an accumulator produces an enormous effect on its efficiency. If, for example, an E.P.S. accumulator be over and over again carried round the cycle of being charged up to 2·4 volts per cell, and discharged down to 1·8 volts per cell, the charging and discharging currents being the maximum allowed by the makers—viz., 0·026 ampere per square inch in charging, and 0·029 ampere per square inch in discharging—the "*working efficiency*" thus obtained may be 97 per cent. for the ampere-hours and 87 per cent. for the watt-hours. If, on the contrary, the cell be constantly charged up before being tested, then, for the first few charges and discharges between the above limits, and with the same current density in charging and discharging, even the *energy* efficiency may be as high as 93 per cent. ; whereas, if the accumulator has been left for some weeks, then, although it was left charged, the energy efficiency for the first few charges and discharges will be as low as 70 per cent.

While, on the one hand, our tests show that continued rests of a charged accumulator appear to be far more serious for the accumulator than we had previously imagined, the working efficiency appears to be higher than has hitherto been supposed, since we believe that about 84 per cent. efficiency in the watt-hours is all that the advocates of accumulators have claimed for them.

The smallness of the first discharge after a rest might be due either to a kind of electric short-circuiting and dissipation of the energy, or to some change in the character of the active material converting the energy perhaps directly into heat, or to some of the active material having become disconnected from the plates during the rest and having fallen down to the bottom of the cell. The smallness of the first *charge* subsequently to the first discharge after the rest, shows that mere electrical leakage during that time has not been the cause of the loss of energy, while the steady increase in the storage capacity brought about by a series of charges and discharges tends to show that rest brings about some change in the nature of the active material.

In all the tests in which the results are given in the preceding table, the charge and discharge were, as already stated, terminated when the potential difference per cell reached a fixed value ; it is, therefore, possible that the apparent falling off in the capacity of the cells to store energy may be due to a change in the resistance of the cells produced by the rest. For a change in the resistance of the cells will change the terminal potential difference for a given current flowing through the cells without there being any necessary change in the storage capacity.

It is, therefore, interesting to study the variations in the shapes of the potential difference curves 8 to 23. First, as regards the charge curves, 9 and 11 are convex everywhere to the axis of time except just when the charging is commenced ; whereas 13, the steady working charge curve after the second rest, rises much more rapidly when the potential difference cell is about 2·3 volts than is the case in the other two curves, then bends over and becomes concave to the axis of time. This peculiarity in curve 13 is, we notice, not very striking in the small reproduction of this curve in the text, but in the original curves as plotted on large sheets of squared paper from the results of the tests, the difference between curves 11 and 13 is very noticeable.

The following list gives the time in hours and minutes from the commencement of the charging when the potential difference per cell reaches 2·2 volts :—

Curve 9 ... 7h. 14m. .. Steady working charge before rest.
„ 11 ... 7h. 32m. ... „ „ „ after first rest.
„ 13 ... 7h. 10m. ... „ „ „ „ second rest.
„ 15 ... 5h. 36m. ... „ „ „ „ third rest.
„ 17 ... 3h. 54m. ... First charge after fourth rest.
„ 19 ... 5h. 43m. ... Steady working charge after fourth rest.
„ 21 ... 4h. 50m. ... First charge after fifth rest.
„ 23 ... 4h. 40m. ... Steady working charge after fifth rest.

It is clear, then, that the effect of a series of rests is to cause the potential difference to rise much more rapidly in subsequent charges, and the time curve rise of potential difference still remains unusually steep, although at the end of every rest there was a prolonged and uninterrupted series of charges and discharges.

Curves 16 and 20, which gives the values of the potential difference for the *first* discharges after the fourth and fifth rest, show that for the first hour from the beginning of each of these discharges

Digitized by Google

the potential difference *rises instead of falling*, as is the case in normal discharges.

If the rapid fall of potential difference at the commencement of a discharge be due to a disappearance of gases occluded in the plates, as some have supposed,—or if, as Dr. Gladstone and Mr. W. Hibbert imagine, the charging of a cell causes the acid round the positive plate to become denser than that round the negative, and the mixing of the denser and less dense acid at the commencement of the discharge causes the potential difference to fall,—then the absence of this fall at the beginning of a discharge after a long rest would be explained; but neither of these theories would apparently explain the rise of the potential difference obtained by us at the commencement of a discharge after a long rest. Indeed, the fact that it required two discharges and two charges after a long rest before the discharge curve (the third after the rest) acquired its normal form, tends to show that this rise of potential difference at the commencement of the first discharge after a long rest is due to some other cause.

Again, Prof. Duncan and Mr. H. Wiegand have shown in their communication that the diffusivity of the sulphuric acid into the plugs is greatest at the end of the charge, and least at the end of the discharge. Hence, if it be the diffusing out of the strong sulphuric acid from the plugs of the positive plate that causes the rapid fall of E.M.F. on breaking the charging circuit at the end of a charge (see Figs. 3, 4*, and 11†), one would hardly expect that it would be at the *end* of a discharge, when the diffusivity of the acid in the plugs was a minimum, that the rise of E.M.F. on breaking the discharging circuit would be most rapid, but that numerous experiments have shown us to be the case. In fact, curve No. 8, Fig. 11†, shows that towards the end of the charge the E.M.F. falls from 2·298 to 2·274 volts in 20 seconds after breaking the charging circuit, and similar curves that we have drawn from our experiments on the time rise of E.M.F. on breaking the discharging circuit show that towards the end of the discharge the E.M.F. rises from 1·951 to 1·970 volts in 20 seconds, the latter rate of rise being almost exactly equal to the former rate of fall.

All the rests already referred to occurred when the cells were fully charged; but before these long rests took place the cells, when in their formal state, were on one occasion allowed to remain discharged for 34 minutes, with the following result:—

Cells in Normal State.

Time taken to complete—

Charging 11h. 38m.
Discharging 10h. 10m.
Next „ 11h. 37m.
Next „ 10h. 12m.
Next „ 11h. 37m.
Next „ 10h. 11m.

Cells here remained discharged for 34 minutes.

First charging after rest, 11h. 50m.
First discharging after rest, 10h. 15m.
Next charging after rest, 11h. 42m.

These results emphasise the fact that accumulators are damaged if left discharged, even for a short time; and it was for this reason that during the whole of this investigation the cells were never left discharged for a longer time than was necessary to change over the connections from discharge to charge, except on this one occasion, when it was desired to ascertain the magnitude of the change produced by leaving the cells discharged for a short time.

It is interesting to notice that the effect of discharging cells too low, or of leaving them discharged, is to increase the times required for the subsequent chargings, whereas the effect of leaving them charged is to diminish the times required for the next chargings.

VIII.—*Chemical Action.*

Dr. Frankland has shown that probably the discharge of an ordinary accumulator is accompanied by the formation of one or other, or both, of the new lead salts which he has isolated, and which have the formulæ ($Pb_3S_2O_{10}$) and ($Pb_5S_3O_{14}$) respectively. And he concludes that, in view of the great difficulty of electrolytically splitting up the well-known white sulphate of lead ($PbSO_4$), this sulphate is not formed in the ordinary discharge of the accumulator, and is only produced when the cell begins "to sulphate."‡

Prof. W. Kohlrausch and C. Heim show in their Paper already referred to that the observed variations in the specific gravity of the liquid during charge and discharge agree well with the very simple chemical actions—

Charge.

Positive plate—
$$PbSO_4 + 2\,H_2O + SO_4 = PbO_2 + 2\,H_2SO_4.$$
Negative plate—
$$PbSO_4 + H_2 = Pb + H_2SO_4.$$

Discharge.

Positive plate—
$$PbO_2 + H_2SO_4 + H_2 = PbSO_4 + 2\,H_2O.$$
Negative plate—
$$Pb + SO_4 = PbSO_4.$$

It is to be noticed, however, that the falling off in the specific gravity during discharge is merely a test of the amount of H_2SO_4 that is converted into H_2O, and affords no criterion as to what sulphate of lead is formed by the SO_3 liberated.

During our investigation we observed the variation in the specific gravity of the liquid during about 100 charges and discharges, and the mean of this large number of the fairly consistent results that we obtained showed that, with the accumulators we were testing, the variation in density per ampere-hour was about 0·000·232. This result is probably right to within 5 per cent., for our hydrometer would read accurately to about 0·001, which is about 5 per cent. of 0·03, the total change in specific gravity observed during the discharge; and, therefore, as each result is correct to something like 5 per cent., the mean of a hundred results will certainly be correct to within 5 per cent.

On referring to tables of the density of dilute sulphuric acid, we find, by plotting the results, that between the limits we are concerned with—1·2 and 1·17—the change of density is directly proportional to the amount of SO_3 taken from the solution; and, further, that to produce a change in density of 0·01 at 15° C., it requires that 1 gramme of dilute sulphuric acid of density 1·2 should give up 0·01268 of a gramme of SO_3. And as the liquid in each cell weighed about 10,490 grammes when the cell was charged and the density 1·2, it follows that the weight of SO_3 liberated per ampere-hour in each cell, when calculated from the variation in the specific gravity, must equal—

$$\frac{0{\cdot}000232}{0{\cdot}01} \times 0{\cdot}01268 \times 10{,}490 \textit{ grammes},$$

or

3·086 grammes.

Further, the electro-chemical equivalent of SO_3 is 0·000414 grammes per coulomb; and since lead sulphate is formed on both the positive and negative plates during the discharge, the weight of SO_3, taken out of the liquid per ampere-hour, when calculated from the electro-chemical equivalent of SO_3, must be

$$2 \times 3{,}600 \times 0{\cdot}000414 = \textit{3·041 grammes}.$$

These two results show a close agreement. At the same time, it is to be noticed that not merely does the amount of SO_3 liberated per ampere-hour come out somewhat higher when calculated from the *mean* change in the specific gravity than when calculated from the chemical equivalent, but the same result is obtained for each separate set of tests.

Mr. G. H. Robertson, working in Dr. Armstrong's laboratory, was so good as to analyse the sediment that fell to the bottom of the cells during the early part of the investigation, when in the discharges the potential difference was allowed to fall to 1·6 volts per cell. The mixture was found to contain—

An indication of uncombined metallic lead,
A trace of antimony,
40·95 per cent. of combined lead } *i.e.*, 47·3 per cent. of PbO_2

Dr. Frankland's salts may be represented as $PbO_2\,2(PbSO_4)$ and $2(PbO)\,3(PbSO_4)$ respectively, whereas the analysis of the deposit in our cells showed that it was certainly neither of these lead salts, but, instead, had almost the exact composition of PbO_2, $PbSO_4$.

In spite of accumulators with pasted plates having been in use now for nine years, the chemical action that takes place during the different stages of the charge and discharge has only been conjectured, and, odd as it seems, no decisive experiment appears to have been made to settle this much-debated question. Various analyses have been made by different chemists of salts of lead acted on in certain ways with sulphuric acid, but apparently not of actual accumulator plates in action. We are therefore now, with the assistance of Mr. Robertson, making a complete investigation of

the chemical state of the plugs of both the positive and negative plates at all stages of the charge and discharge of an 1888 E.P.S. type of accumulator in good condition. As this investigation, however, involves the chemical analysis of a large number of specimens, it will take some time yet to complete.

In order to observe what changes took place in the temperature of the cells during charge and discharge, the temperature of one of the cells under test was observed from time to time, as well as the temperature of the air and the temperature of an adjacent cell through which no current was being passed. The above temperature results, which were obtained during the steady discharges and charges after the first rest of ten days (curves 10 and 11), are a sample of the observations taken. The discharge in each case commenced directly the potential difference, in charging, had reached 2·4 volts per cell, and the charge in each case commenced directly the potential difference, in discharging, had fallen to 1·8 volts per cell.

From the preceding table we see that, while during the charge the cell rises in temperature, during discharge, on the contrary, it actually falls; hence, in spite of the production of heat due to resistance, the cell is actually cooler at the end of a discharge than at the beginning—a result possibly due to the splitting up of the sulphuric acid during the discharge. This cooling of accumulators during discharge, which we noticed early in our experiments, was also observed at about the same time by Prof. Duncan and H. Wiegand in America and described in their joint investigation already referred to.

From the last table we see that the rise of temperature of the cell during charging may, after allowing for changes of temperature of the room, be either about 1·3° C. or 0·77° C., while the fall of temperature during discharging may have either of the two preceding values. It is further interesting to notice that the rise of temperature during the charging has the higher or the lower of these two values according as the fall of temperature during the previous discharge had the higher or the lower value.

On plotting the differences between the temperatures of the working and the idle cell and the corresponding times given in the last table, we obtain the dotted line 24 (Fig. 8) for the time fall of temperature during the first and third discharge, curve 25 for the time rise of temperature during the first and third charge, curve 26 for the time fall of temperature during the second and fourth discharge, and curve 27 for the time rise of temperature during the second and fourth charges. 24 is dotted, since temperature readings were only taken at the beginning and end of the first and third of these discharges. In the case of the second and fourth of the discharges here referred to, as well as in all the four charges, several observations of temperature were made. From the curves it appears that towards the end of the discharge and at the beginning of the charge one or other of two things may happen—either the temperature in the discharge may go on falling, as in the dotted line 24, or it may begin to rise again, as in 26; whereas, in the charge, either the temperature at the beginning may rise considerably, as in curve 25, or it may only increase slightly, as in curve 27.

It would therefore appear that during the latter part of the discharge one or other of two chemical actions can take place; and these two actions have, for some reason or other, taken place alternately in the four discharges under consideration. But, curiously enough, these four discharges—which took place on July 10th, 11th, and 12th, 1889—occurred with extreme regularity; so that when time curves were drawn, even on a large scale, for each of these discharges, they coincided exactly and produced a single curve, which is shown, greatly reduced, as curve 10 on the sheet of curves given in the earlier part of the Paper. And, similarly, for the four corresponding charges the four time curves all coincided exactly, producing a single curve, which is shown, greatly reduced, as curve 11 on the same sheet. It, therefore, seems as if one or other of two chemical actions might take place during the latter portion of the discharge and during the earlier part of the charge, and yet, curiously enough, when the current is kept absolutely constant the time variation of the potential difference is exactly the same, no matter which of these two chemical actions takes place.

Fig. 8.

About a year later another set of *continuous* temperature observations was made for many days and nights with the same cells, the current in discharging and charging being, as before, 10 and 9 amperes respectively. The higher potential difference limit was, as before, 2·4 volts per cell, but the discharge was in each case in this second set of continuous discharges and charges stopped at 1·9 instead of 1·8 volts per cell. As the regulation of the current day and night was in these later experiments in 1890 effected by hand, it was not kept quite as constant as when the automatic regulator was employed. Hence the time curves for the excess

Digitized by Google

temperature in discharging and charging, when plotted, were not found to be as regular as in the previous case. But they were quite regular enough to give the general shape of the sets of temperature curves for discharge and charge which are shown in Fig. 9.

It will be observed that in these experiments not merely does the excess of the temperature of the working cell over that of the idle cell fall during the discharge, but it actually continues to fall at the commencement of the charge.

The times of discharging and charging are less than those given for curves 10 and 11, partly because the potential difference was not allowed to run down lower than 1·9 volts per cell in the later observations, and partly because the times of discharging and charging had been diminished by the continued experimental rests to which these cells had been subjected in a charged state during 1889.

The mean temperature of one of our cells is during charging and discharging, roughly, 0·7° C. higher than that of the air; and experiment shows that if one of the cells experimented on be warmed up by a portion of the ordinary dilute sulphuric acid being replaced by warm sulphuric acid of the normal density, the cell will, after all parts of it have acquired a uniform temperature, fall in temperature by 0·2443° C. per hour per 1° C. excess of temperature. Of course, during such an experiment no current is allowed to pass through the cell, nor should any current have passed for hours before the heat emissivity of a cell is determined, otherwise a wrong value of the emissivity may be obtained by local action in the cell generating or absorbing heat during the experiment.

Difference of Temperature of Working Cell and of Idle Cell
Discharge
Charge
0 1 2 3 4 5 6 7 8
Time in Hours from Beginning of Discharge or Charge

FIG. 9.

Hence, if K be the heat capacity of the cell, $0·7 \times 0·2443 \times K \times 21\frac{1}{2}$ calories (gramme, Centigrade) will be lost by radiation and convection during the $21\frac{1}{2}$ hours of charging and discharging. Now the weights and specific heats of the component parts of one of the cells under test are—

	Weight in Grammes.		Specific Heat.
Dilute acid, sp. gr. 1·9	10,490	...	0·792
Lead and lead oxide ...	12,987	...	0 0315
Glass	3,402	...	0·198

Hence, 0·2443 K equals 2,295 calories, and the loss of heat in charging and discharging equals 34,520 calories. The total watt-hours given to a cell in charging was 228·2 (see Curve 11, for the *working* results obtained with the cells after the first rest of 10 days), therefore the energy in calories given to the cell was $0·24 \times 228·2 \times 3,600$, or 197,200 calories. Hence, in consequence of the cell being slightly warmer than the air during charging and discharging, there is a loss of energy from radiation and convection equal to about 17 per cent. of the energy put into the cell, and this is more than sufficient to explain the total loss observed in the energy efficiency experiments, which amounts to only about 13 per cent. Indeed, it would almost seem as if a portion of this heat radiated must be supplied by an actual slow consumption of the material of the cell; so that, in addition to the reversible oxidation and deoxidation of the material, which is the characteristic of the secondary cell, there was a certain amount of non-reversible oxidation, which is the characteristic of the primary cell.

The loss of energy in consequence of the current having to overcome the resistance of the cell is of far less importance than the loss of energy due to the actual continuous radiation and convection from the cell, which is slightly warmer than the air. For the mean resistance during discharge of one of the cells experimented on may be taken as 0 004 ohm (see Section IX., Resistance, Figs. 12 and 13), and the mean resistance in charging as 0·0045 ohm. Hence, during the normal 10 hours of discharge with 10 amperes there will be generated,

$$0·24 \times 10^2 \times 0·004 \times 10 \times 3,600, \text{ or } 3,456 \text{ calories,}$$

and during the normal $11\frac{1}{2}$ hours of charge with 9 amperes,

$$0·24 \times 9^2 \times 0·0045 \times 11\frac{1}{2} \times 3,600, \text{ or } 3,621 \text{ calories.}$$

Only, therefore, 3,456 calories need be dissipated during the discharge of a cell, and 3,621 during the charge, in consequence of the heat produced by the current overcoming resistance; and to dissipate this amount of heat it would only be necessary that the mean temperature of the cell should exceed that of the air by about 0·14° C., or only about one-fifth of the actual mean excess. Whereas what actually takes place is that during discharge about 16,060 calories are dissipated by radiation and convection; and, further, the cell cools down, possibly in consequence of the splitting up of the sulphuric acid, and from 6,000 calories in some experiments to 12,000 in others are thus absorbed. During the charge these 6,000 or 12,000 calories reappear warming up the cell, and, in addition, about 18,460 calories are dissipated by radiation and convection.

In order, then, to improve accumulators, what has to be especially sought for, and, if possible, then prevented, is that chemical action which keeps the mean temperature of the cell about 0·7° C. above that of the air. This chemical action is very possibly quite distinct from the reversible one which necessarily accompanies the storing up of the electric energy and its subsequent liberation.

(To be continued.)

THE CONTINUOUS-CURRENT TRANSFORMER AT THE CHELSEA COMPANY'S STATION AT DRAYCOTT-PLACE.

In the description of the above Company's station and sub-stations which appeared in *The Electrician* of May 30th last we mentioned the use which is to be made of continuous-current transformers, and also that one was already being arranged for testing. We are now able to give some particulars with reference to this machine. In appearance it resembles a two-pole inverted type Elwell-Parker dynamo. The armature is of the drum type, the two windings being upon the same core, and a commutator for each is arranged at opposite ends of the armature. The machine has been constructed by the Electric Construction Corporation (Limited), and has given very satisfactory results during the time it has been under test. The output for which the machine is intended is 33,500 watts, and the speed 1,000 revolutions per minute. There is obviously a necessity for extra precaution in insulating the high and low tension circuits from each other in the armature of the transformer on account of the mechanical stress.

The method adopted by the designers of the machine has been to wind up the primary into thin ebonite troughs, which are laid along on the surface of the armature. This has proved efficient so far. The insulation resistances, which have been steadily rising since the commencement of the tests, is at the time of writing as under:—

Between the windings .....17 megohms.
,, the thick wire and frame of machine..... 7·5 ,,
,, the thin wire and frame of machine..... 9 ,,

A test has recently been made of the performance of the transformer, the readings and the results of which are given in the table below.

	Primary.			Secondary.			
	E.M.F. at terminals.	Current.	Watts absorbed.	E.M.F. at terminals.	Current.	Watts delivered.	Commercial efficiency.
1	604	72·5	43,790	111·5	320	35,536	81·3 %
2	606	72·5	43,935	111·5	327	36,313	82·5 %
3	588	64	37,632	110·5	280	30,814	82·2 %

Mountain Railway at Barmer.—From the *Frankfurtre Zeitung* we learn that it has been decided to use electricity as motive power on this line. The work will be entrusted to the firm that is constructing the Elberfeld-Barmen line, the contract price being 900,000 marks (£45,000).

THE SUBWAY DISPUTE IN NEW YORK.

The subway system of New York, if system it can be called, appears to be likely to lead to difficulties as serious as those which it was intended to avoid. As soon as the overhead wires were condemned, several companies were formed to make subways. To tunnel or build a subway in New York is a more serious undertaking than to carry on the same work in the soil of London; and as everything of this nature is treated as a political matter in the United States, the complications of promoters and their policies become very formidable. Several more or less organised bodies mortgaged, or otherwise, disposed of their rights, franchises, and such property as they had acquired, to the Consolidated Telegraph and Electric Subway Company, which is said to have a capital of £625,000. The operations of subway-making for electrical purposes are controlled by a law which provides that the City of New York may, after January, 1897, purchase the system of tunnels, together with their fixtures and rights, for a sum not exceeding the actual cost of the property, with ten per cent. added. Under these conditions, it was natural that the pro-

Digitized by Google

moters should have set to work to recoup themselves with more energy than is usual in an undertaking which is not hampered by any such prospective limitation. The Western Union Telegraph Company, which owns the majority of the telegraphic systems of the United States, together with the Bell Telephone Company, were not backward in the matter, and managed to acquire a powerful control of the whole affair. But this did not suit the arrangements of certain patentees, who, of course, had been busy in devising methods of construction. The North-American Underground Telegraph and Electric Company was one of these, and they brought an action in the Supreme Court against the Consolidated Company for an alleged breach of contract in failing to use their patent system of conduits. The North-American Company, however, assert that the Western Union Telegraph Company and the Bell Telephone Company, being "practically the owners and controllers of a certain other corporation known as the Metropolitan Telephone Company," had for their own purposes so managed and controlled the affairs of the Subway Company, and had conspired to prevent the placing of the wires underground, that they claimed damages at £520,000. They also demanded that the Subway Company should proceed to take down overhead wires in New York and place them in their (the North American) patent conduit. It is alleged that the Subway Company had agreed with the North American Company to use a certain conduit made on the Johnstone system. This was laid throughout several miles of streets when operations were suddenly suspended. The stoppage is attributed to the action of the Western Union and Bell Telephone Company, who are said to have such influence with the Metropolitan Telegraph and Telephone Company as to control indirectly the Subway Company; but they appear to push their complaints rather far when they assert that the Consolidated Company have resorted to building useless conduits in order to induce the public to imagine that an underground system is impracticable.

The Consolidated Company, having acquired mortgages of the lesser corporations, have themselves mortgaged £240,000 of bonds to the Atlantic Trust Company, while the Edison Company is mixed up with it to the extent of £24,000, and other electric companies to £240,000. Similar amounts are given to the Mercantile Trust Company, and the whole are payable in June, 1894, at an interest of 6 per cent., or, at the option of the Company, they may be redeemed earlier, at six months' notice on payment of accrued interest and a 10 per cent. premium on the par value.

The counsel for the Brush and two other important electric companies says that, at the outset of the subway movement, two or three years ago, there was some opposition on the part of the United States and the Brush Companies to the use of subways, from an honest belief that it had not been demonstrated that underground distribution was successful. The Westinghouse interests had favoured underground distribution from the beginning. Mr. WESTINGHOUSE preferred to work underground. The Brush and United States Companies now encourage the building of subways, and place their conductors in them as fast as they are ready. They only complain that they are not built fast enough, being convinced by a year's experience that they suit their work and afford a valuable protection to their wires.

We do not suppose that such an extraordinary difficulty as that which exists in New York could take place between rival companies in this country. We have, at all events, some recognised system of obtaining powers to take up streets, after due application and compliance with the regulations of Parliament and the Board of Trade. If a company were formed to carry out in London the work which the Empire City Subway Company proposes to undertake, we believe that several of our supply companies would be ready to avail themselves of the facilities they offer. This company was incorporated with a capital of a little over £100,000, with the object of constructing, manufacturing, maintaining, equipping, operating, leasing or selling conductors, subways, conduits, ducts, and house connections. It would save a very considerable amount of trouble and expense to a London supply company if it could dispense with the worries and red tape that are met with in dealing with vestries and other local authorities, besides enabling a considerable reduction to be made in their staff and plant. The local authorities have been encouraged by Mr. CHAMBERLAIN, and their powers have been materially extended owing to his suggestions. The Board of Trade defer to them in a way that was unknown ten years ago; and the uncertainty as to what will be the nature of their authority five years hence makes it difficult to speculate on the probable result of any matter with which they have to deal. The view of some of the local authorities is that all the new industries of supply—gas, water, hydraulic service, pneumatic tubes, and electric light—impose additional limitations to their control of the streets, and that having had their powers set aside by so many Acts of Parliament, they should have some voice in any new regulations that are made. So far as the control of the streets is concerned, it is probable that the vestries and local boards would recognise the advantages of a subway system; but no sooner does a discussion commence upon a subject in which so many interests are involved, than the leading principle is lost sight of, and the matter becomes so modified and amended that little or no interest in it survives.

REVIEWS.

The Electrical Engineer's Pocket-Book. By H. R. KEMPE. (London: Crosby Lockwood and Son, 1890.)

This is a well arranged and compact pocket-book, and will be very useful both to the telegraphist and to the electrical engineer. It contains 250 pages, besides some sheets of squared paper, and is $\frac{5}{8}$ of an inch thick. It is easy to excuse errors of omission in a pocket-book, since every page saved increases its portability. The greatest fault of the most successful pocket-book—"the indispensable Molesworth"—is its attempt to cover too much ground. Mr. Kempe has doubtless carefully considered the question of the double field of his work, when he has deliberately combined telegraphy with heavy electric engineering. He has Molesworth as a precedent; but we think he makes a mistake. A telegraphist's note-book might be compiled, with about 160 pages, making a book say $\frac{3}{8}$in. thick; and to do this, Mr. Kempe has merely to cut out those pages relating to electric lighting, metallurgy, engines, dynamos, &c. He might compile another pocket-book, embodying the pages discarded from the first, together with much matter, such as resistance of wires, that is common to both subjects. But the second work would, unless it were considerably modified, be distinctly inferior to the first.

The author has evidently expended great pains in the arrangement of the tables. The very first line in the book, which we thought contained an error, is a proof of this. The weight of one cubic foot of water is given as 62·355lbs. Every engineer is familiar with the common 62·425lbs.; but, on closer examination, we find, and we did not remember, that the latter refers to water at its maximum density, while Mr. Kempe assumes (though he does not say so) 62° Fahr. Several neat approximate conversions of metric into English measure are given, and these are supplemented by the percentage of the error which they involve. An excellent rule,

Digitized by Google

which we have often used, but which we have never before seen in print, runs:—If two approximate values have to be *multiplied* together, take one value too high, and the other too low, the errors will then tend to cancel each other. If two approximate values have to be *divided* the one by the other, take both values either too high or too low. Among the units we find the calorie, but no mention of the English unit of one pound of water heated 1° Fahr., as used by all engineers. In giving the effect of temperature on electrical resistance, it should be stated that most pure metals follow the same law as copper. We searched in vain some months ago through every book we could find, for the effect of temperature on the resistance of platinum, and discovered nothing but an extremely elaborate Paper on the subject in the *Transactions* of the Royal Society, which gave minute accounts of experiments with curves and theories, and everything about platinum, except the coefficient, which we learned afterwards is the same as that of copper. The sections on testing and measurement are excellent; but we object to the term "joint conductivity resistance," where the joint resistance of two or more wires in parallel is meant. The term "parallel" seems to be carefully avoided throughout the book, and the old expression "multiple arc" is used.

The sections relating to electric lighting, &c., are, as we have intimated, below the high standard of the rest. It is asserted, probably on the authority of Prof. Silvanus Thompson, that a constant-current dynamo can be arranged by providing an independent constant excitement for a shunt machine. This we believe to be impossible. No less than four pages are devoted to as many diagrams of the methods of connecting for series, shunt, separate excitation, and compound. These, together with several other items, are text-book matters; no engineer should need to refer to a pocket-book to refresh his memory about such subjects. One is reminded of the story of the Japanese engineers in charge of a steam engine, who, when an accident was imminent, became so excited that they forgot the formula for stopping it.

The old form of Prony brake with blocks, screws, and lever should be supplemented, if not replaced, by the arrangement of ropes used at the tests of gas engines made by the Society of Arts. No engineer's pocket book is complete without a trigonometrical table, and more space should be devoted to it than is given by Molesworth. In a table of the consumption of fuel, high speed engines are placed at one end of the list, with a consumption of 3·5 to 4lbs. single cylinder high pressure engines 3 to 3·25, single cylinder condensing 2·5 to 2·62, and compound condensing 1·87 to 2. Nothing is said about the size of the engines; and the table as it stands, gives the impression that the engines of, say, Messrs. Willans and Robinson are the most uneconomical of any. The "dictionary of technical terms" which occupies the last 13 pages, might be compressed into less than half the space in smaller type. But who wants to consult a pocket-book to learn what "Armature, Dynamo" means, and there to find that it is "the moving part of a dynamo in which the currents are generated"? The definition of impedance is as careless;—"resistance to the flow of the electric current." But what can we say about the "Positive plate of a voltaic cell?" "The plate from which the current is assumed to flow from the external circuit. The zinc plate and Potential, Electric. The power of doing electric work!"

Notwithstanding these slips, the "Electrical Engineer's Pocket-Book" is a good one, and we venture to suggest that some of our hints might be adopted in a future edition which is sure to be called for at no distant date.

Edmunds on Patents for Inventions. (London: Stevens and Sons, 1890.)

This is, we think, the most complete work on the Law and Practice of Letters Patent for Inventions we have seen. The author gives as his apology for his work that the last really comprehensive treatise on the subject—though, of course, there have been many most useful and efficient minor publications of limited scope—was published by Hindmarch in 1846, that is, prior to the Patent Law Amendment Act of 1852, which made many important and radical changes in the law, but which has itself been superseded by the 1883 Act, under which, and its amendments up to the present date, the practice and procedure both in regard to applications for and grants of letters patent for inventions is almost in every respect different from what it was at the time of Hindmarch's work of 1846. The object, therefore, of the present work is commendable, and will supply the deficiency alluded to.

The book under review deals with its subjects in a thoroughly exhaustive and able manner. It is divided into three parts, each carefully arranged, so as to avoid, as far as possible, confusion, and facilitate reference. We have not space to enumerate the heads of all the subjects individually, as dealt with under these headings, and it must suffice to say that in addition to the new matter introduced by the author in Part I., which occupies 423 pages, there are the Patent Acts and Rules annotated, the International Convention, and a full collection of statutes, forms, and precedents. The history of the law is dealt with, and the functions of the Patent Office. The text contains references to all the precedent patent cases which are now of any importance, dates and contemporary references being also given. Tables are supplied of cases brought up to date, and an appendix of Statutes, Rules, and Forms under the most recent (1890) rules, &c. The author has included an appendix of foreign and colonial patent laws; this latter we think might, perhaps, have been dispensed with, since the book is already of somewhat unwieldy dimensions, and might with advantage have been divided into two volumes. It concludes with a well-arranged and copious index.

The treatise has obviously entailed an enormous amount of labour, care, and knowledge, and it deals with its many-headed subject in an exhaustive manner. It should prove of value to patent agents and others interested in or likely to require information on the subject, and is well worthy of a place in the library of solicitors and others who may from time to time have to deal with the subject of letters patent for inventions and collateral matters connected therewith.

Electricity in the Diseases of Women. By G. Betton Massey, M.D., Physician to the Gynæcological Department of Howard Hospital, &c. Second edition. (London and Philadelphia: F. A. Davis.)

That this little work should have run through one edition within a few months of its first appearance is a sufficient indication that it has supplied a want, and, therefore, to a certain extent, criticism is disarmed.

The exact value of electricity as a curative agent is still somewhat uncertain; the whole question may be very truly said to be yet in its infancy. It is frequently the fate of great discoveries that their first introduction is retarded, on the one hand, by strenuous opposition, and, on the other, by the over-zeal of enthusiasts; out of this conflict of opinions we arrive, in course of time, at a true estimate of the real value of the innovation. We should not like to say that this "true estimate" has yet been attained in the case of medical electricity, but Dr. Massey's book is an example of the process referred to; in it electricity no longer appears as the universal panacea, and no hesitation is evinced in bringing forward cases in which its application was followed by bad symptoms, or in enumerating those in which its use is distinctly contra-indicated. We do not ourselves feel in a position to offer any opinion upon the purely medical aspect of the subjects treated by Dr. Massey; more especially as, in spite of the powerful advocacy of some eminent members of the medical profession in this country, the methods of Dr. Apostoli, with which the work before us is mainly concerned, can hardly be said to be universally accepted or practised in England.

For the rest we may say, that the electrical principles involved are explained in a clear and readable manner, and without undue references to elementary or theoretical considerations. The diagrammatic contrast (Figs. 11 and 12) of the electrical force with a column of falling water strikes us as a particularly happy one, and likely to save the student much time and trouble in his efforts to appreciate the differences between "electromotive force," "resistance," &c. The author has introduced an ingenious "current controller" (Fig. 3), the action of which depends upon the contact surface afforded by a carefully graduated band of graphite; he insists, too, upon the use not

Digitized by Google

only of carefully controlled currents, but also upon exact measurements of current-strength. The importance of this latter can never be over-estimated in scientific work; and it becomes an absolute necessity when, as in the class of cases treated by gynæcologists, currents of upwards of two hundred milliamperes are dealt with.

The book is decidedly well worth reading, even by medical men who have not devoted themselves especially to the study of diseases of women.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

(Continued from page 318.)

§ 7. **Cables at Rome.**—The current supplied by these machines is conveyed into three main conductors, often called the feeders. These consist of concentric cable made by Siemens and Halske, laid in wooden boxes filled in with cement and placed underground.† The construction of this conductor is well known. It consists of a core of stranded copper wires, insulated over with an insulation of jute impregnated with highly insulating material. Outside this is stranded the return conductor of copper wires enclosing the core, as in a tube; then more insulation, and finally a double twist of iron

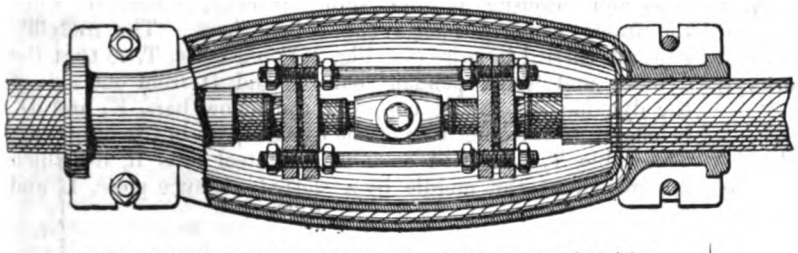

FIG. 21.—Simple straight-joint Coupling in Siemens and Halske Concentric Cable.

or steel tape and hemp protection over that. In Rome there are some 18 to 20 kilometres, or about 12 miles, of this main cable laid up to the present (1890). The cross section of each conductor is 220 square millimetres, or about one-third of a square inch. The main cables are laid in 100 metre lengths, with junction-boxes at this distance.

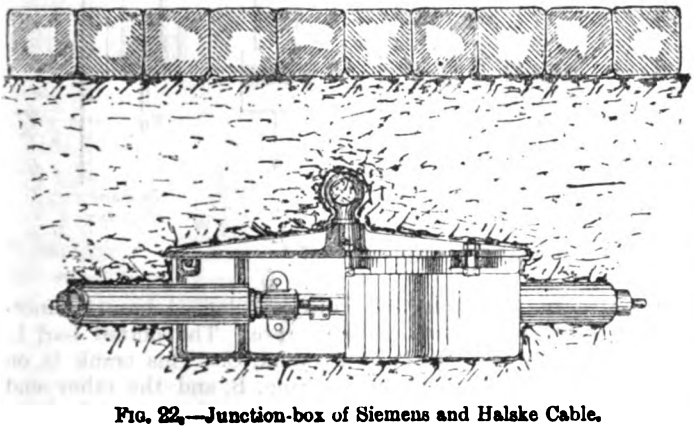

FIG. 22.—Junction-box of Siemens and Halske Cable.

The three main cables all run together to the Piazza Venezia and then diverge off in different directions, the most distant point reached being about 4½ kilometres, or three miles, from the station. The distance from the station to the point of divergence is about 1,600 metres, or one mile. The mode of making the junctions of the different lengths of the cables and of the branches has been most carefully thought out. The junctions are made in cast-iron boxes, in which these junctions are formed by copper straps, links, or clamps, and involve no soldering in making the joint in the street. The lids of the boxes are closed water-tight, and the box then pumped full of rosin oil. The diagrams in Figs. 21, 22, 23, and 24 show the various forms of junction box and mode of making the joint. Beyond the Piazza Venezia, the three mains give off branches in different directions, smaller concentric cable being used and the sub-mains run to the different groups of transformers. At the present date (1890) there are some 125 transformers installed, all being of the same uniform size of 7,500 watts, or 10 horse-power. These transformers are put in singly or in groups

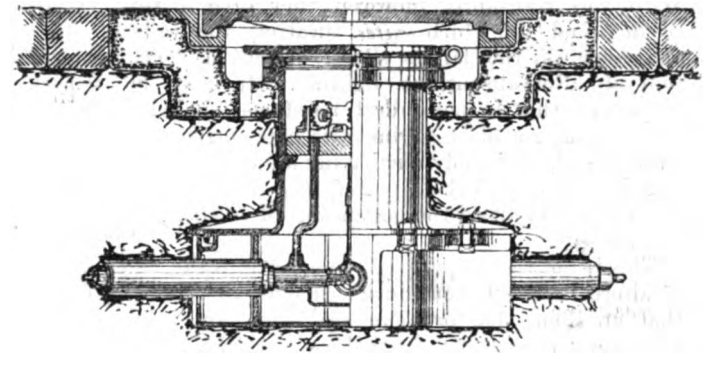

FIG. 23.—Surface-box for branch junction, Siemens and Halske Cable.

arranged in parallel in the various houses and public buildings, and feed about 12,000 100-volt incandescence lamps of 16 candle-power, 10 candle-power, and 32 candle-power, as well as some 300 Ganz alternating arc lamps of 8, 16, and 32 amperes, which are worked off the intermediate terminals of the transformer. The transformers are placed in small fire-proof safes, boxes, or chambers, according to their number, and

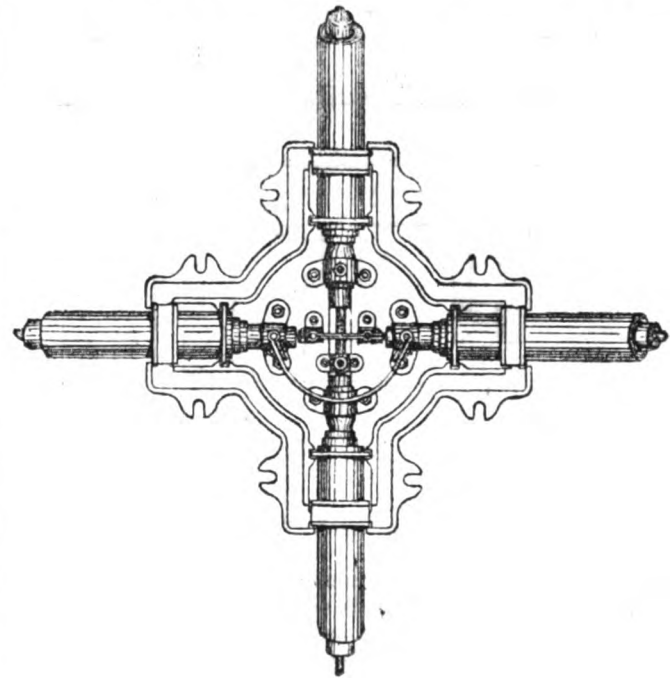

FIG. 24.—Cross-junction, Siemens and Halske Cable.

great pains are taken with the insulation of the primary wires. Bare copper rod is most used for connections and is carefully carried on porcelain insulators, in the transformer rooms where it is possible to do so. In other places highly insulated wire. The transformers each take at full load about four amperes of primary current at 2,000 volts, and give out 75 amperes at 110 volts; the intermediate terminal enabling arc lamps with resistances in series

* All rights are reserved.

† This plan of laying in cement has not been found to be satisfactory. In future it is probable the concentric cable will be laid in wooden troughing filled in with pitch or asphalt.

Digitized by Google

to be put on at 55 volts. A number of 10 horse-power transformers banked together is used in each of the large buildings lit. The lighting comprises not only street arc lighting, but lighting by arc and incandescent entirely of theatres, Senate and Chamber of Deputies, post, telegraph and public offices, besides shops and houses; the extreme variation of potential from point to point not being greater than 4 volts, and being regulated from the Central Station by keeping a standard pressure at one of three points in the network. The Argentina Theatre is lit by 1,800 incandescent lamps, and 11 arc lamps, worked off 12 transformers, having their secondary circuits in parallel. Each arc lamp has a resistance in series with it which absorbs about 10 volts, and without this resistance the arc lamps are not found to work steadily. With this resistance, however, they give a very excellent result; and the chief *cafés*, theatres, the railway station, and some of the larger shops, present a very fine exhibition of alternate-current lighting. It may be remarked in passing that a mere dead resistance should not be used for the purpose of steadying alternate-current arc lamps. A choking coil, preferably one having an air gap in it for reasons already given (*see* Vol. I., p. 267, *The Alternate-Current Transformer*), would afford the best means of securing the necessary steadiness.

This is not the proper place to enter into the vexed question of alternate *versus* continuous current arc lamps. The fact that at Rome 300 or more arc lamps are being employed indicates the necessity for making provision for arc lighting; and the economical question which has to be faced is whether the gain in simplicity of working by a uniformity of system is or is not counterbalanced by the disadvantages of intrinsic economy in the alternating parallel-worked arc as compared with series-worked arcs of equal mean candle-power, operated on separate circuits and by separate machines and, perhaps, engines.

§ 8. **Change-over Switch** (Zipernowsky, Déri, Bláthy).—Although the dynamos in the Central Station at Rome are of different sizes, it has been found perfectly possible to work them in parallel together. As a regular rule this is not done, but each one of the three mains is supplied by a separate dynamo according as the load on it requires. As there are six dynamos and three main conductors the problem presented was to connect any one of the six dynamos to any one of the three mains, and to make any necessary change in the combination without extinguishing the lights. This has been solved by the construction of an exceedingly ingenious switch-board which effects these changes with ease and certainty. The switch is an elaborate arrangement, and somewhat costly to construct. It will best be understood by the following diagrammatic sketches.

On a suitable framework is carried a series of pairs of copper bars (see Fig. 25) D_1, D_2, D_3. D_1 and its fellow (not shown) are in connection with the poles of one dynamo. Similarly, D_2 and its fellow are in connection with the poles of a second dynamo, and so on. These bars are carried on insulators, and have pendant iron rods, d_1, d_2, d_3. There are a second series of pairs of copper bars, F_1 and its fellow (not shown), F_2 and F_3, and so on, which are in connection with the two leads of various cables. From these bars F_1, F_2, &c., are also pendant iron rods f_1, f_2, &c., and these are placed near the pendant rods, d_1, d_2, &c. Mercury cups, 1, 2, 3, &c., can be raised or lowered by a mechanism to be described, by which these pendant rods can be put in electrical connection, so that f_1 is joined to d_3, or to d_2, or to d_1, according as mercury cups 1, 2, or 3, are raised up. Hence, we see that the bars, D_1, D_2, D_3, can be electrically joined to the bars, F_1, F_2, and F_3, pair and pair, in any combination; and we must suppose that the fellow bars not shown in the figure, but which are the duplicate bars for the other side of the dynamo, are coupled similarly simultaneously. Suppose, for instance, that the mercury cups, 1, 5, 9, are raised up and the rest kept down; then D_3 is joined to F_1, D_2 to F_2, and D_1 to F_3. Thus, any dynamo can be put on any cable. Supposing that each dynamo is working on a cable, and it is desired to interexchange the positions of the dynamos, this can be done by raising and lowering mercury cups. For instance, let D_1 be joined to F_3, and D_3 to F_1, and let it be requisite to interchange the dynamos. What has to be done is to lower the mercury cups, 1, and 9, and raise the mercury cups, 3, and 7, and, if this is done very quickly, the dynamos and circuits will be interchanged without any sensible interruption of current. The mechanism for raising one group of mercury cups and lowering another, simultaneously, is carried below the frame which supports the copper bars. The mercury cups are carried in pairs (*see* Fig. 26) on a table, T, so that the dynamo and feeder pendant bars, F, and D, from one side of the dynamo, dip in one cup, and the fellow bars, F', and D', belonging to the other side of the dynamo, dip in the other cup. This table, T, is carried on a pair of steel rods R, R', which are crossed at the middle by a slotted distance piece, L, and

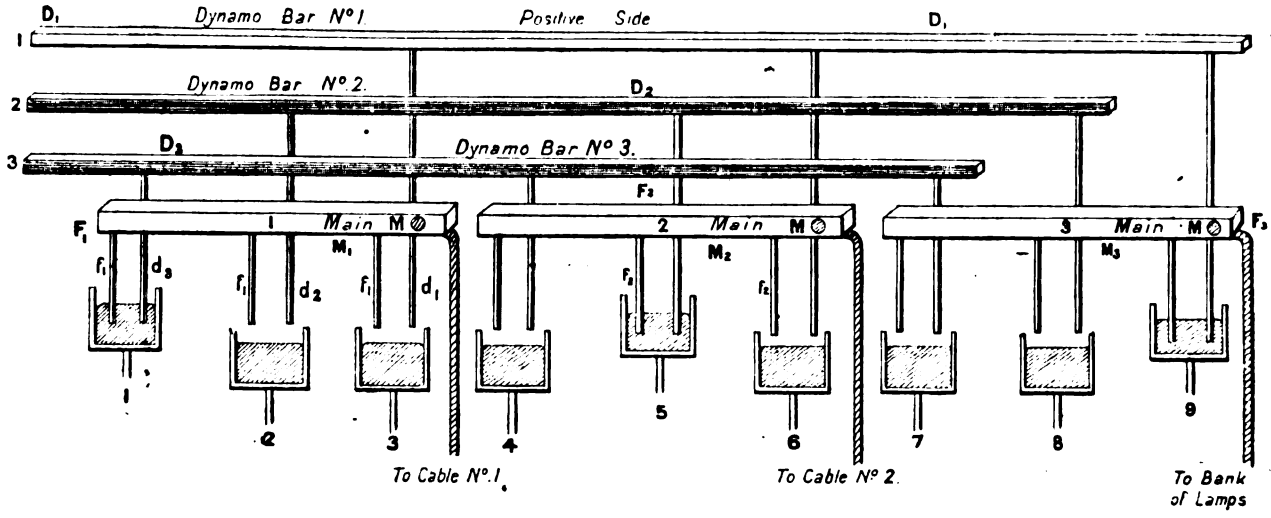

Fig. 25.—Diagram representing one side of change-over switch in central station, Rome.

the weight of the table and cups is balanced by a balance-weight below, not shown in the figure. The slotted bar, L, is traversed by the pin, P, of a crank, C. This crank is on a shaft, Q, working through a bearing, B, and the other end of the crank is supported by a pin, *p*, working in a bearing in the back of a slotted block, S, the slot in which is just wide enough to receive the square web of the crank, C, when the shaft, Q, is pushed forward by the handle, H, as far as it can go. When the shaft, Q, is pushed forward so that the crank arm, C, engages in the slot in the block, S, it is easily seen that the crank can only be moved round with the mitre wheel, W; but that when withdrawn it has an independent motion of rotation. By turning the handle, H, when the crank is disengaged from the block, S, the mercury cups can be raised or lowered through the distance of the "throw" of

Digitized by Google

the crank, but, if the crank is engaged in the block, S, then the rise and fall of the table can be effected by a rotation of the wheel, W. The crank can be obviously turned or inserted into the block, S, either in the upper position or in the lower, and then a half-turn of the wheel, W, will either lower the cups or raise them.

Imagine a series of such cranks placed side by side (see Fig. 27) and each supporting its table and pair of mercury cups; and suppose the mitre wheels, W, attached to each shaft to engage in a series of mitre wheels, W', all keyed on one long shaft. If a handle, K, is given half a turn, it will turn all the slotted blocks, S, half round, and it will raise, or lower, or not move, the table corresponding to each crank, according as that crank has been engaged previously in the slotted block in the upper or lower position, or withdrawn so as not to engage at all.

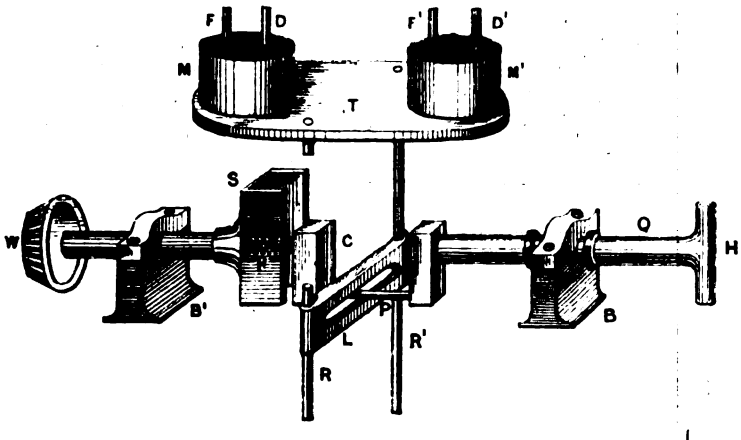

Fig. 26.—Diagram representing Cranks for Raising or Lowering Mercury Contact Cups in Change-over Switch at Rome.

It is, therefore, obvious that by an appropriate position for each handle, any of the pairs of mercury cups can be caused to rise, or fall, or not to be moved, when the handle, K, is turned half round. Returning to Fig. 25, we can now see that a mechanism can be suitably arranged to effect simultaneously the electric connection or disconnection of any dynamo from any main, and that any possible combination can be instantaneously exchanged for any other.

In the change-over switch at Rome there are four pairs of bars corresponding to the three mains, and to a bank of 3,600 lamps which is used as an artificial load on which to run up each dynamo to speed.

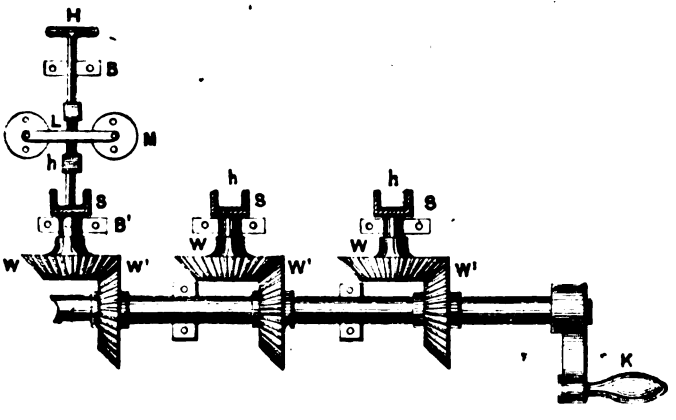

Fig. 27.—Diagram of Mitre-wheel Arrangement in Change-over Switch at Rome.

If any main is being operated by any dynamo and it is desired to replace this dynamo by another, the incoming dynamo is first run up to the same amperes and volts as that of the circuit dynamo it is about to replace. The change-over switch is then brought into action to interchange the dynamos working on the circuit and that working on the artificial load; and so perfect is the operation of this switch that, when smartly worked, not the slightest wink can be seen on the circuit lamps. This switch is used to replace the small day dynamos by the bigger ones, at nightfall, and when required, or to effect any interchange necessary. It is, no doubt, an expensive switch-board to construct, but it does its work admirably.

(To be continued.)

PICKING-UP MACHINES FOR CABLE SHIPS.

In connection with Mr. H. D. Wilkinson's recent article on "Improvements in Cable Ship Gear," a few particulars of the machinery first used in repairing cables may, we think, prove of interest to our readers.

The first example is the recovering of the Donaghadee and Port Patrick cable, which had been paid out for sixteen miles, when the tide and wind swung the ship round stern to wind and tide, and the cable had to be cut about five miles from the land in about 180 fathoms.

Mr. R. S. Newall had a picking-up machine made, consisting of two drums of equal diameter, with grooves and spur-wheels, which geared into a pinion between them. The cable came from the bow sheave to the sternmost sheave, took half a turn in a groove, and then went under the foremost sheave half a turn round, and on to top of the sternmost sheave, on to the second groove, and so on for five half turns on each drum. The machine was fitted on board the Electric Telegraph Company's ship "Monarch" (the first telegraph ship), which had been chartered by Mr. Newall, and the whole sixteen miles were recovered. This machine was never used again.

In 1854 Mr. Edwin Clark and Mr. F. C. Webb designed the first single-drum picking-up machine. It was made to work with handles, which extended to bearings on the gunwale on each side, so that some twenty men could be put on to each handle, and several lifts were thus executed by manual power. There was a ratchet-wheel attached to the drum to prevent accidents in case the cable was deep in the ground and the ship pitching. But soon an engine was used, with a strap from the fly-wheel of the engine to a pulley on the last pinion shaft. The drum had a knife to fleet the turns, as on a paying-out drum. There was no hauling-off gear, and the cable had to be kept tight by men hauling at it. A hauling-off gear was added about 1857. The drum had bearings on both sides, so that the cable could not be got off without cutting it.

In 1863 Mr. F. C. Webb designed the machine for the "Amberwitch," the repairing ship for the Persian Gulf cable. In this machine the bearings are both on the same side of the drum, which is carried on an overhanging shaft. The turns of cable can be taken off therefore, without cutting the cable. A pinion worked into an internal spur-wheel, and was attached to the drum on the outside of which was the brake. By having the spur gearing connected to the drum itself, no strain was thrown on to the spokes of the drum, which was the case when the spur-wheel was on the shaft and detached.

There were two knives for fleeting, the one in front for picking up, and the other behind for paying out. To take the turns on the drum off, the stern knife had to be moved away from the drum. This was effected by taking out a cotter, which was provided with a handle, when the knife fell away from the drum, and the turns could then be taken off. There was a hauling off gear to this machine, which slid sideways on its shaft, so that when the turns of cable moved from one side (when picking up) to the other side (when paying out) the grooved wheel could adjust itself to the proper position. This machine did its work for a good many years in the Persian Gulf; but of course there are many improvements now, though Mr. Webb is of opinion that the large spur-wheel should be always attached to the drum, and not, as in some machines, even of recent date, be separated from one another, thus throwing a strain on the spokes of the spur-wheel, and on those of the drum, besides torsion on the shaft, and a strain on all the keys. The machine fitted to H. M. telegraph steamer "Monarch" has these defects.

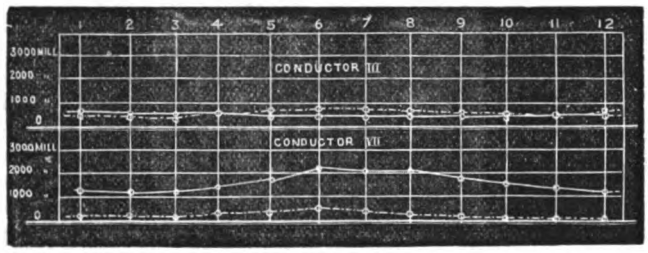
INSULATION MEASUREMENTS ON SOME GERMAN UNDERGROUND CABLES.*

BY C. GRAWINKEL.

The German underground cables have since their laying been subjected to regular tests and measurements at the hands of the Postal Telegraph Engineers' office. These observations, extending now over a number of years, lead to important conclusions as to the behaviour of the cables. The measurements taken relate to the resistance of the conductors (seven in number) constituting the cable, the capacity, and the insulation resistance. Of these, the two former are of comparatively small importance, whereas careful records of the insulation resistance extending over a considerable time, may offer some guide as to the direction in which improvements are to be sought. It is on the properties of the gutta-percha covering then that interest is concentrated.

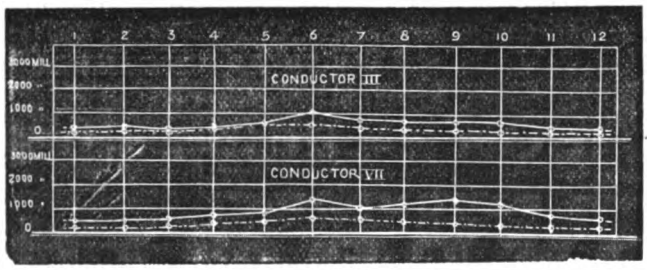
The oldest of the cables is that from Berlin to Halle, regular measurements of which have been taken since 1877, those most recently laid being from Berlin to Danzig, Thorn, Posen, and Stettin, for which measurements since 1882 are at hand.



FIGS. 1 and 2.—Berlin-Halle.

The results of some of the measurements are shown in Fig. 1. The insulation resistances of definite conductors, reduced to one kilometer in length and a temperature of 15°C., are shown by the curves, the mean values for each month in millions of Siemens' units being the ordinates, and the abscissæ representing the time, the Figs. 1 to 12 standing for the months of the year. In each case the full line shows the first available measurements, whilst the dotted lines are those for the year 1889.

Figs. 1 and 2 give the results in the cases of conductors 3 and 7 of the Berlin-Halle cable for the years 1877 and 1889, and Figs. 3 and 4 those for the Berlin-Hamburg cable in 1879 and 1889. The Berlin-Hanover cable shows similar curves.



FIGS. 3 and 4.—Berlin-Hamburg.

The curves for these cables show a great resemblance. It will be noticed that the insulation rises during the summer months, as is shown particularly clearly by conductor 7. Conductor 3 also shows this to a smaller extent for the year 1889, the maximum occurring in June and July. The curves for conductors 1, 2, 4, 5, and 6, which with 3 surround conductor 7, are not given, as they are similar to that for 3. It is surprising to find that whilst the insulation of conductor No. 7 has in all three cables dropped considerably (notably in that from Berlin to Halle), that of No. 3 has dropped very slightly, and is even in some cases higher than its original value.

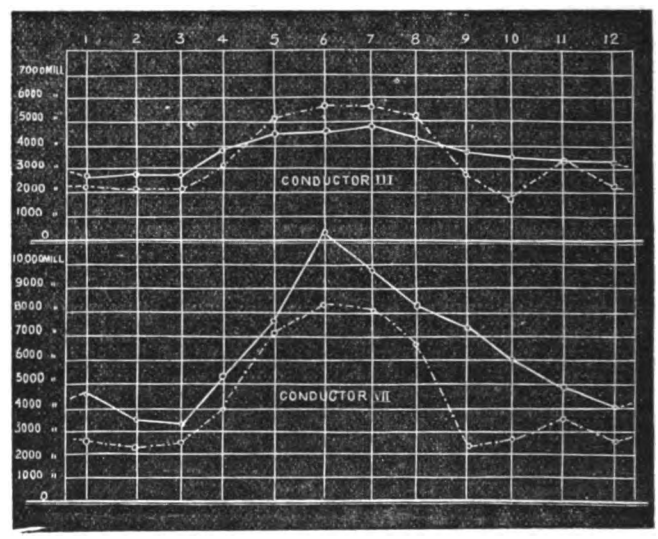
In Figs. 5 and 6 are given the measurements for 1881 and 1889 for the cable to Frankfurt-on-Oder. The Dresden and Thorn cables present the same features.

These curves again show a rise in insulation during June and July. On conductor No. 3 the value is sometimes above and sometimes below that taken in the earlier year; whereas No. 7 shows a general fall, although at times it also rises above its original value.

It will be seen that these cables divide themselves so far as regards their insulation into two classes. In the one, including the first laid cables from Berlin to Halle, laid 1876; from Berlin to Hanover, laid 1878; and from Berlin to Hamburg, laid 1877, the variations are small; whilst in the second, including the cables from Berlin and Frankfurt-on-Oder and Breslau, laid in 1880, Berlin to Dresden, laid in 1879, Berlin to Posen and Thorn, laid in 1880; Berlin to Stettin, laid in 1881, the fluctuations are of considerable magnitude.

Before proceeding with the deductions to be drawn, a short explanation of the way of carrying out the measurements may be given. The resistance of a core of a conductor is first measured by means of a Wheatstone bridge. From the known normal resistance at 15°C., the temperature at which the cable stands can be determined, and then by the help of a correction-table drawn up for every half degree, the insulation at the normal temperature can be obtained. At this point it should be noted that it is not likely that the whole of a long cable will be at the same temperature, considering that it is laid along streets, on and under bridges, and even carried through watercourses. The measured resistance of the conductor gives only the sum of the resistances of the various parts at their respective temperatures. The mean temperature determined in this way will give rise to errors in arriving at the insulation resistance with the help of the temperature corrections. To show this by means of a simple example it may be supposed that half of a cable is at a temperature as much above 15° C. as the other half is below that point, so that the mean temperature is still 15° C.

If the insulation resistance of the whole cable at 15° C. is R, that of each half is 2 R. At a temperature $t°$ higher the insulation resistance of the half is $2\,R\,a^{t}$, and that of the other half at $t°$ lower is $2\,R\,a^{-t}$, where a is a constant, which is approximately



FIGS. 5 and 6.—Berlin-Frankfort-am-Oder.

equal to ·876. These two resistances must be regarded as in parallel, so that the total insulation resistance of the two halves is

$$\frac{4\,R^2}{2R\,(a^{t}+a^{-t})}=\frac{2\,R}{a^{t}+a^{-t}}$$

The ratio of the two resistances, R and $\frac{2\,R}{a^{t}+a^{-t}}$, ought to be = 1. Instead of this, however, it will be found (by expanding) that the ratio is equal to

$$1+\frac{(t\log a)^2}{2}+\frac{(t\log a)^4}{24}+$$

$\log a$ being = − ·132.

The second term in the correction may be neglected, the error arising from this being only ·7 per cent. when $t=5$.

The corrections thus required are—

t	1°	2°	3°	4°	5°
Error per cent.	·9 ...	3·5 ...	7·8 ...	14·9 ...	22·7

No sufficient observations are at present available to determine the range of temperature at which the various parts of a cable may be.

It may therefore be pointed out that other variations in temperature may affect the result obtained, besides those derived from the measurements of the resistance of the copper core. According to the yearly returns of the meteorological station at Eberswalde in 1886, at a depth of ·9m. (that of the cable being usually 1m.), the lowest temperature observed − ·1°C. was in the middle of March, the highest, 17·8°C. on September 5th. Cable measurements on the Berlin-Frankfort line gave − 1·6°C. on March 12th, and 19·8°C. on September 10th.

* Abstract of a Paper read before the *Elektrotechnische Verein.*

These considerations, however, must be applicable proportionately to all land cables, and they therefore cannot account for the great difference observed between the two classes of cables.

The ordinary theory of insulation with regard to time (assuming the properties of gutta percha to be always the same) should give a straight line for each cable. The curves for the first three cables do not differ greatly from a straight line, whereas the others do, so that the fluctuations must be assigned to different causes in the two classes. The cause can only be sought for in the quality of the gutta percha covering, so that the insulation depends on the gutta percha used as well as on dimensions and temperature. It is highly probable, therefore, that the constant given above for gutta percha as 0·876 is not applicable to every specimen of that material, and the special figure for any particular cable must be known in order to judge of its behaviour.

It is possible that the quality of the material varied owing to the extraordinarily heavy demand for it during the years in which the extensive German networks were laid down. At the same time the great difficulty of determining the absolute resistance of gutta percha prevents this being regarded as a proof, although the curves seem to admit of no other explanation. Further investigations in this direction will take place.

It remains to investigate the conclusions to be drawn from one pair of curves. In the summer months the insulation regularly rises. This cannot be imputed to errors of observation. The cause lies in the fact that the surface of the earth is gradually drying up, so that in spite of the rise of temperature, no fall in resistance takes place.

Another point is that the insulation of conductor 7 has fallen very considerably, according to the measurements of the last years. In all the cables it has the highest resistance, being surrounded by the other six conductors. The fall in insulation can only be attributed to the fact that moisture gradually penetrates with the yarn which fills the space between the conductors, and so the properties of the covering of No. 7 in time change, and No. 7 approaches in insulation resistance the other six.

It will be seen that measurements in the case of land cables present important difficulties. Few of these enter in the case of marine cables: these lie throughout their length in water, and differences of temperature at various points cannot exist, and the insulation resistance can hardly vary. Conclusions with regard to the behaviour of a land cable are not to be trusted, until specific resistance at normal temperatures is determined with greater certainty. The ordinary test for cables, by immersing a fixed length in warm water, affords no criterion for their behaviour when laid underground, and it is only by careful observations continued for a considerable length of time that any valuable result can be obtained.

THE DISCHARGE OF ELECTRICITY THROUGH GASES.*

BY ARTHUR SCHUSTER, F.R.S.

"If we accept the hypothesis that the elementary substances are composed of atoms, we cannot avoid concluding that electricity also, positive as well as negative, is divided into definite elementary portions, which behave like atoms of electricity."—HELMHOLTZ (Faraday Lecture).

A gas in its normal state contains no free ions, but if through any chemical or physical causes the molecules are broken up in an electric field, ions form, and the gas becomes a conductor. Supposing the difference of potential of two electrodes is gradually increased, a point will be reached at which a spark will pass, that is to say, the molecules will be broken up by electric forces, the positive ions diffusing towards the kathode will tend to form a polarising layer of finite thickness, increasing in width as the pressure diminishes. If the discharge becomes steady, the decompositions are continuously kept up at the kathode, the negative ions being projected with great velocity away from it. These ions will move through the so-called dark space without much loss of energy by impacts; but when, probably owing to sufficient diminution in the electric force, the impacts become more frequent, the translational energy becomes transformed into the luminous vibrations of the glow. The positive ions forming an atmosphere round the kathode must have a greater velocity the nearer the kathode, where their energy becomes visible in the first luminous layer. Whether decompositions take place only at the electrode or through a finite distance from it, is at present an open question; nor can we decide as yet whether the negative molecules projected outwards are the main carriers of the current inside the dark space. In the dark space the negative ions will accumulate and meet the positive ions proceeding from the positive part of the discharge. We shall expect at some point towards the outside of the glow the free ions to become more numerous than in other parts of the discharge. Here we find a small fall of potential and no luminosity; this is the dark interval separating the positive part of the discharge from the negative glow. A number of ions probably reunite in this part to form molecules, and in case it should ultimately be found that positive and negative ions diffuse with the same velocity, we should have to conclude that as many molecules as are decomposed at the kathode recombine in this dark interval. If, as seems more probable to me, it should be found that the negative ions diffuse more rapidly, the recombination will in part take place at the anode. If the conditions in the tube are such that the gas may divide into layers, such that in alternate strata the decompositions outnumber the recombinations, and *vice versâ*, stratifications will form.

Such is the general outline of the theory, which may have to be modified in detail, but which I believe has a strong element of truth in it.

The possibility of a volume electrification is denied by some of Maxwell's disciples, who look on a current of electricity as on a flow of an incompressible liquid in a closed circuit. But there is nothing, as far as I can see, in the conclusions I have drawn from the gas discharges which is inconsistent with the fundamental tenets of Maxwell's theory, however much they may disagree with the accessory embellishments with which that theory is occasionally adorned. There may be a volume electrification without interfering with the equation of continuity of an incompressible liquid as long as we admit the possibility of displacement currents and displacements in conductors; and I see nothing improbable in this. The ordinary equations for the currents in a non-homogeneous solid (or any solid if inequalities of temperature are taken into account) give a volume electrification which can only be destroyed by the introduction of a quantity which is analogous to hydrostatic pressure, and the sole purpose of which is to destroy all electrifications except at the surface of bodies. We know of no physical phenomena which can justify the introduction of such a quantity, which seems to me unnecessary. The existence of a volume electrification can be shown to exist when a current passes from one liquid to another floating on its surface. Chemical effects are observed in the region in which the liquids begin to mix, and these can be explained by the electrification which accompanies each change in electric conductivity. Maxwell's equations assume conductors to be homogeneous throughout; whenever we are dealing with average effects only, this assumption is justified. We deduce, in a similar way, the equations which represent the transmission of light by assuming that each transparent body is replaced by a homogeneous medium having certain properties. But although this simplification is allowable in discussing some of the phenomena, there are others in which it becomes necessary to go a step further, and, considering the structural constitution of the body, to take into account separately the effects of the medium separating the atoms, and the effects of the atoms themselves. In all branches of physics we are gradually forced by the advance of knowledge to abandon the assumption of homogeneousness, and if that is done, no further difficulty stands in the way of bodily electrifications; for we may take them to be really only surface electrifications between the atoms and the medium.

I have offended in another manner against so-called modern views of electricity, for I have spoken of positive and negative electricity as real substances possessing a separate existence. I have tried to place myself, however, under the shelter of recognised authority by quoting at the top of this lecture Helmholtz's saying that we have as much ground for the supposition that electricity has an atomic constitution as we have for the atomic constitution of matter. We must trust to the future to bring this view into harmony with the electro-magnetic theory of light, which may be accepted now as an established fact. There is no real antagonism between the two views. If ever we are able to explain chemical and gravitational attraction by the stresses in a medium, we shall still find it convenient to speak of atoms and molecules; and in the same way the belief in an electric strain and stress is consistent with a belief in something in the atom from which the strain proceeds, and which may be taken as the elementary quantity of electricity. Even taking the extreme view that electric stress is due to vortex filaments in the ether, we need only assume all these filaments to have the same intensity, and some to end at the surface of atoms, in order to reconcile apparently antagonistic views. But there is no need to commit ourselves at present to any particular ideas. In some electric phenomena we shall find it most convenient to speak of electric strain and stress (displacement I think to be a misleading term, which, however, has come too much into use to be dispensed with); in other, and at present more numerous, cases, we shall still continue the old nomenclature, and speak of positive and negative electricity as real quantities. The subject of electro-chemistry is one of primary importance in the present state of science. The different behaviour of positively and negatively electrified particles points, as I have tried to explain, to an unsymmetrical modification of molecular forces by electrification. It is not sufficient to add geometrically the effects of molecular and electrical action, but it is necessary to take account of the inter-

* Concluding section of a preliminary communication to the Royal Society. Received and read March 20, 1890.

Digitized by Google

ference between chemical and electrical forces. The exact nature of this interference must partly be solved by chemical investigation, but the discharges of electricity through gases still promise a rich harvest to the investigator.

THE ELECTRICAL TRAMWAY IN PARIS.

Experiments with the working of tramways by electricity are being continued in Paris by the Northern Company on the line between Levallois and Madeleine. Four cars are practically worked, and the Société Française d'Accumulateurs Electriques (Faure-Sellon-Volckmar), who supply the motive-power at the rate of 3d. per car and kilometre, are of opinion that the traffic will be permanent. The motive power is furnished by Faure-Sellon-Volckmar accumulators, with double plates. The batteries are divided in twelve boxes, each containing nine elements coupled in series, 108 cells in all, and as each element weighs 15 kilos., the total weight of the battery is 1,620 kilos.

The twelve boxes are placed in cupboards in the corners of the car—four in front and eight behind. The connections are so arranged that the elements, when the boxes are fixed in their places, become automatically ranged in groups of three by three boxes behind each other, so that there are four groups in all of twenty-seven elements ranged after each other. These four groups may be connected for work in four different ways, as at the Birmingham tramway.

The various connections are effected by the aid of a commutator, consisting of a wooden cylinder, with contacts on the surface. The cylinder is turned by a handle.

The electrical motor is of Siemens' construction, and situated below the car in front. The number of revolutions may be raised to 1,600 a minute, but under normal working it is 1,000. The power is transmitted to the wheels of the car through gearing, which reduces the speed in the proportion of twenty-six to one.

The motor is reversed by the use of a double set of brushes. The cars weigh 3,500 kilos., there being 1,600 kilos. of accumulators and they carry 50 persons. During ordinary speed of 11 kilometres (6·85 miles) an hour the electrical work required is as follows:—On level road, 4·3 horse-power (16 amperes × 200 volts); on incline of 1 in 100, 7·8 horse-power (29 amperes × 200 volts); on incline of 1 in 50, 11 horse-power (42 amperes + 200 volts). With a speed of 9 kilometres (5⅝ miles) an hour and an incline of 1 in 33, 12·3 horse-power (46 amperes × 200 volts) are required. On an incline of 1 in 25, 15·3 horse-power (57 amperes × 200 volts). Finally, with a speed of 5 kilometres (3 miles) an hour and an incline of 1 in 20 the force is 10·2 horse-power (38 amperes × 200 volts), and on an incline 1 in 18 10·75 horse-power (40 amperes × 200 volts).

ELECTRIC LIGHTING IN ST. PANCRAS.

An elaborate report of the Electricity Committee of St. Pancras Vestry—the only local authority in London which has decided to provide the electric light on its own responsibility—was presented on Wednesday last to the Vestry. The Committee reminded the Vestry that the latter authorised them to obtain plans, specifications, estimates, and tenders for carrying out a first installation for the supply of electricity for the purposes of light and motive power of an extent sufficient for 10,000 incandescent lights; the mains being sufficient for 25,000 lights of 16 candle-power each and 90 arc lights. The Committee had divided the work into seven sections, and invited a tender for each. The Committee recommended that tenders amounting in the aggregate to £50,946. 4s. 3d. be accepted. Although having every confidence in their engineer, Prof. Robinson, the Committee had thought it well to submit the plans and specifications to Dr. Hopkinson, President of the Institution of Electrical Engineers, and Mr. Preece, F.R.S., Chief Electrician to the Post Office. Mr. Preece, in his report, stated that "he had in many cases been called upon to consider the best system that should be adopted in various districts. He considered that in selecting the Direct Continuous Current System they had done quite the best thing. He regarded the plans and specifications as very complete, as thoroughly considered, and well worked out." Finally, Mr. Preece observed, "I think that the Vestry of St. Pancras is doing a wise thing in carrying out this installation, and I see no reason whatever, from the careful consideration I have given to the plans submitted, why it should not obtain all the results that have been foreshadowed. The ratepayers will secure the light at the cheapest rate, and the profits accruing from private lighting can be devoted either to the reduction of rates, or to the expense of public lighting." The committee recommend that the seven tenders mentioned in the report be accepted, viz:—

1. Buildings, Kirk and Randall	£4,629	0	0
2. Boilers, &c., the Babcock and Wilcox Company	3,674	10	6
3. Engines, dynamos, &c., Willans and Robinson	16,327	0	0
4. Switchboards, the Electric Construction Corporation	1,313	1	9
5. Batteries, the Electric Construction Corporation	2,745	12	0
6. Trenches for five miles of mains, Mowlem and Co.	9,501	0	0
7. Electrical conductors, 5 miles for private lighting, and 5½ miles for public lighting, Clark, Muirhead, and Co.	12,756	0	0
Total	£50,946	4	3
Add for royalty	909	0	0
Total	£51,855	4	3

It was decided to defer the consideration of the Committee's report.

THE DOUBRAVA ARC LAMP.*

The principle of this lamp is shown by Fig. 1. A and B are fixed electro-magnets, placed one at the top and the other at the bottom of a parallelogram consisting of rods of soft iron, which constitute their cores. C and D are movable solenoids, each sliding no one of the vertical portions of the parallelogram, which at the same time form cores for the solenoids. P is a pulley over which passes a cord, from the ends of which the solenoids C and D are suspended: below these are fixed the carbon holders E and F. When a current traverses the electro-magnets A and B the cores become magnetised, and their poles N N S S arrange themselves as shown. In a like manner, when a current passes through the solenoids C and D, two poles *N N*, *S S* are formed; so that in the solenoid C the pole *n* is attracted by the pole S of the parallelogram and *vice versâ*. A downward motion, indicated by the arrow, will thus be imparted to the solenoid C.

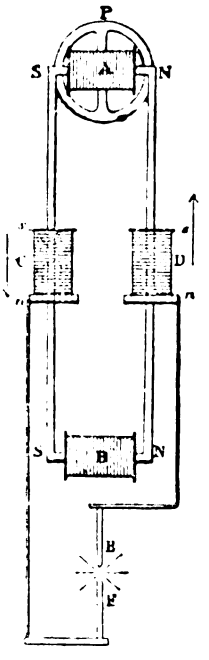

Fig. 1.

In the same way it is obvious that the solenoid D will have an upward motion imparted to it. These two solenoids being connected by a cord passing over the pulley P, their movements take place together, and the carbons are separated. If the direction of the current in the solenoids is reversed, this movement will also be reversed and the carbons will be brought together. On this principle Dr. Doubrava has constructed two lamps, one designed to work in parallel and the other in series.

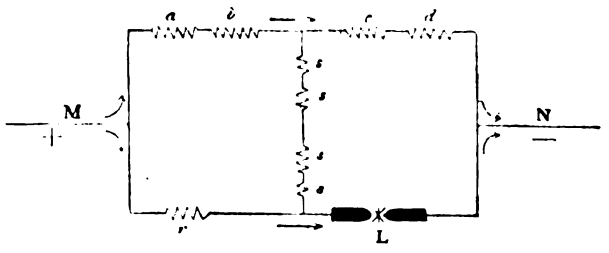

Fig. 2.

The connections of the lamp for parallel working are shown diagrammatically in Fig. 2. The electro-magnets *a*, *b*, *c* and *d* have a resistance that balances that of the arc L and the resistance *r*. S S S and S are four solenoids, which, when the arc is of normal length, should have no current passing through them. When the arc becomes too long a portion of the current goes through the solenoids in the direction M *r s c d* N, and the carbons are brought together. When, on the other hand, the arc is too short, the path is M *a b s* L N, and a portion of the current goes through the solenoids in an opposite direction to that which it formerly did, and the carbons are separated.

Fig. 3 gives diagrammatically the principal connections in the series type of lamp, as constructed by Steinlen and Co., Mulhouse. of A and B are the + and − terminals respectively. E E are the upper and lower electric magnets, S S are the thick wire solenoid coils forming part of the main circuit, and *s s* are fine wire coils arranged as a shunt to the arc. These two coils are, it will be seen by the

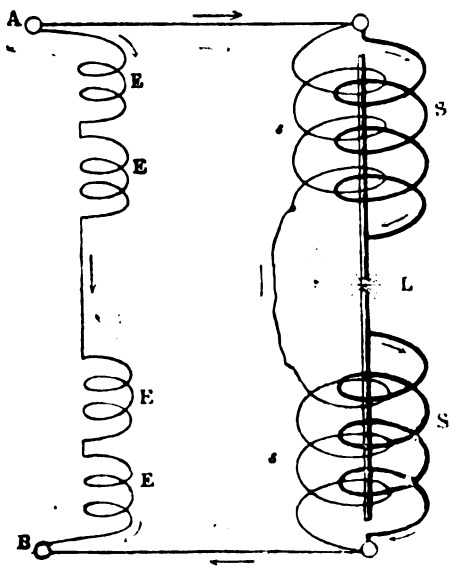

Fig. 3.

figure, arranged to act differentially. This lamp also possesses a cut-out, which introduces such a resistance into the circuit as to compensate for that of the arc. These additions, as well as other modifications, made with the object of perfecting the primary apparatus, are due to M. Schlick, the engineer of the firm of Steinlen and Co.

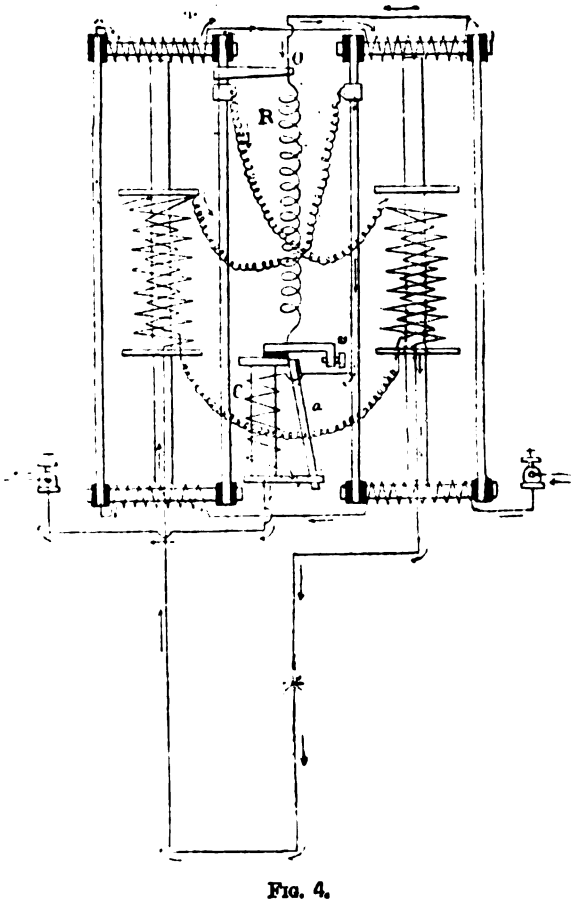

Fig. 4.

The annexed diagram (Fig. 4) shows all the connections in detail of the type of lamp which worked at the Paris Exhibition. The current enters by the + terminal and passes in succession through the four electro-magnets. When it arrives at the point O it is divided into two portions, the most important of which passes through the resistance R, and the armature *a* of the cut-out C, which is not now attracted by the electro-magnet. The current then leaves the lamp of the terminal. The other portion of the current passes through the fine wire of the solenoid, and the thick wire of the cut-out. It is sufficient to actuate the solenoids, and bring the carbons in contact, and thus open a new path of small resistance for the current. The current then passes along the thick wire solenoids, and strikes the arc, the cut-out also attracts its armature, cutting the resistance out of circuit. The feeding of the arc is effected in the manner we have mentioned above. When the carbons are burnt out the armature *a* is brought into contact with *v*, and the resistance R is substituted for that of the arc.

This lamp is extremely simple. The only piece of mechanism it requires is a little catch to prevent the carbons from moving too far apart when the arc is struck. For this purpose the pulley over which the cord passes from which the solenoids are suspended, is provided with ratchet teeth, which come in contact with the catch in question, when the carbons move apart. This catch has, however, a certain amount of play, and the teeth when pressing against it push it by just the amount sufficient to produce an arc of the required length.

LEGAL INTELLIGENCE.

Gibbs and Others v. Ferranti.

In the House of Lords on Friday the case of Gibbs and Others v. Ferranti came before the Lord Chancellor, Lord Herschell, and Lord Morris, in the form of an appeal by Mr. John Dixon Gibbs and the National Company for the Distribution of Electricity by Secondary Generators (Limited) from the decision of the Court of Appeal affirming the judgment of Mr. Justice Kekewich, who, on a petition presented by Mr. Sebastian Ziana de Ferranti, ordered that the Gaulard and Gibbs's patent, No. 4,362, A.D. 1882, should be revoked.

Mr. ASTON, Q.C., and Mr. J. C. GRAHAM appeared for the appellants; while Sir H. DAVEY, Q.C., and Mr. MOULTON, Q.C., represented the respondent.

Mr. ASTON, Q.C., in support of the appeal, said the matter in which this appeal arose was a petition presented by the respondent for the revocation of the letters patent, No. 4,362 of 1882, granted to Lucien Gaulard (since deceased), and John Dixon Gibbs, for a certain invention of "a new system of distributing electricity for the production of light and power;" and the question for decision was whether the letters patent should be revoked. The construction of the secondary generators was fully and clearly described in the specification of the patent; and, as stated by Sir W. Thomson, who was called as a witness for the petitioners, the generators, though not novel, were of special construction, and were described by the patentees, because they were specially adapted to effect the objects aimed at by their invention. The successful working of the new system claimed by the patentees and described in their specification depended upon the conjoined operation of three elements, which were not claimed separately, that was to say—(1), an alternating dynamo supplying electricity in a state of high tension; (2), a long main wire conveying electric currents of high tension in alternate directions, to and through local stations; and, (3) local secondary generators, such as those described by the patentees, operating at each station to supply induced electricity for doing local work. In the year 1884 the invention of the patentees was put into successful operation by the installation of a complete system on the Metropolitan Railway, consisting of a central station at Edgware-road, connected by a main wire about fifteen miles long with local installations at Notting Hill Gate, Gower-street, King's Cross, and Aldgate. An alternating dynamo machine caused alternating currents of high tension to pass along the main wire and generate, by means of the secondary generators placed at each local station, secondary currents, which were successfully employed in the respective stations for lighting purposes. Such use of secondary generators and secondary currents was, as the witnesses for the petitioner against the patent all admitted, wholly new. Not one of them had ever seen or known of such a system of electric lighting having been before used either in the United Kingdom or anywhere else. Since the year 1884 the system of the patentees had been successfully employed at home and abroad, particularly in the United States of America. It was suggested during the trial before Mr. Justice Kekewich, and in the Court of Appeal, that prior to the date of the letters patent a number of propositions had been made and described in the specifications of prior patents for using high-tension alternating currents in a manner similar to that described by Messrs. Gaulard and Gibbs in their specification. It was, however, proved in evidence, and the Court of Appeal were satisfied that it had been proved, that all those alleged anticipations were deficient in material respects. In fact, none of them described the use of the elements whose combined operations made the system of Messrs. Gaulard and Gibbs a success. The specification of the invention patented by Gaulard and Gibbs contained three claims—firstly, the privilege of exclusively working the process of distribution, and the employment of an alternating current of high tension for the generation of an unlimited number of secondary generators and induced currents individually utilised either for the production of light or motive-power; secondly, the system of electric distribution; and, thirdly, the special construction of secondary generators designed to produce this result. After the presenta-

Digitized by Google

tion of the petition, the appellants were advised that the third claim was of doubtful validity, for the reason that it might be said that the secondary generators claimed were not new apart from the system in which it was proposed to use them, as described in the specification, and claimed in the first and second claims. The appellants accordingly applied to Mr. Justice Kekewich for leave to amend their specification by striking out the third claim and certain portions of the specification. On the 21st November, 1887, the learned Judge made an order, granting the leave asked for, and in pursuance of that leave the specification was amended. By that amendment the third claim was struck out, and in other respects the specification was amended; but both before and after the amendment, it in fact described and claimed the invention—that was to say, the combination of elements forming a system of distribution of electricity that was new and useful at the date of the patent. The appellants maintained that that was not the case, and that the sole effect of the amendment was—firstly, to narrow the exclusive grant originally made by the letters patent, by striking out the third claim; and, secondly, to strike out some explanatory passages in which the inventors, by the imperfect lights of the scientific knowledge of 1882, endeavoured to explain the principles on which their apparatus worked, which passages were shown by recent science to be more in the nature of imperfect analogies than scientific statements. He (the learned counsel) contended that the letters patent were valid in all respects; that the specification particularly described and ascertained the nature of the invention for which the letters patent were granted and in what manner it was to be performed; that the specification, when amended, did not claim an invention substantially larger than, or substantially different from, the invention claimed by the specification as it stood before the amendment, and that therefore the decision of the Court of Appeal affirming the judgment of Mr. Justice Kekewich ought to be reversed.

Mr. GRAHAM followed on the same side.

Sir H. DAVEY, in opposing the appeal, contended that as the appellants by their provisional specification indicated the nature of their alleged invention to be a method whereby secondary currents could be obtained from an unlimited number of secondary generators without the primary current being anywise affected thereby, the invention claimed was an impossibility, as it would amount to the obtaining of perpetual motion. By the provisional specification the inventors alleged that their invention consisted in the "employment of an alternating current produced by an electro-dynamo machine, and determining by its passage through an unlimited number of induction coils of special construction the creation of induced currents, whose quality and value depended solely upon the construction of the said induction coils;" and by the complete specification this statement was substantially repeated, and although the latter spoke of the secondary generator to be used as being of special construction, there was no statement or indication in it as to the peculiarities of the alleged special construction, the dimensions of two induction coils of ordinary construction, and possessing no novelty, being mentioned. The claims in the complete specification were:—(1) "the privilege of exclusively working our process of distribution, characterised by the following point, as above explained. The employment of an alternating current of high tension for the generation on an unlimited number of secondary generators of induced currents individually utilised either for the production of light or motive power; (2) the system of electric distribution such as is laid down in the foregoing statement; (3) the special construction as described of secondary generators designed to produce this result." The respondent, however, submitted that the proper interpretation of such claims was that the invention thereby claimed was that of a system whereby secondary currents could be obtained from the primary current without the primary current being modified thereby, so that they could be obtained in unlimited numbers without any corresponding expenditure of power on the primary circuit, and that it was to such an invention alone that the patentees could be entitled under the said claims. Immediately before the date at which the hearing of the said petition would have taken place, the patentees applied for leave to amend their specification and claims, and obtained leave to file a disclaimer by which they struck out of the complete specification all the matter relating to the passage of an alternating current through an unlimited number of induction coils, or the creation of induced currents whose quality and value depended solely upon the construction of the induction coils, or as to forming secondary currents without the primary current being anywise affected thereby. As thus altered, the specification described merely a system of distribution of electricity by means of secondary generators, not purporting to be a mode whereby any number of secondary generators could be worked without loss of power, which was substantially the invention described in the provisional specification. Such alteration made the complete specification, as amended, claim an invention wholly different from that referred to in the provisional specification, and for which the patent was granted. By such disclaimer also the third claim, referring to secondary generators of an alleged special construction, was struck out. The chief witness for the patentees was Dr. John Hopkinson, who, in his evidence, admitted that the invention claimed in the claiming clause was not novel, if it was understood to apply to all secondary generators, and he admitted that the specification did not define or give the differentia of that class, or enable the public to ascertain what generators were or were not within such class; also that it was likely the patentees did not themselves know what was and what was not essential to success. The interpretation of the claims put forward on behalf of the appellants varied at different times during the hearing of the case before Mr. Justice Kekewich to the arguments on the appeal. At one time it was contended that an essential of the invention was that the tension in the secondary circuits should be lower than that of the primary; but it was proved by the admission of the witnesses for the patentees and by the evidence of Sir Wm. Thomson and the other witnesses for the petitioners, that no statement to that effect was to be found either in the claims or in the specification. The attention of Dr. Hopkinson was called in cross-examination to various prior publications referred to in the particulars of objection, and amongst them to the account of Jablochkoff's system of electrical distribution set forth in his specification, No. 1,996 of 1887, and in Du Moncel's book. The witness admitted that this described the employment of an alternating current for the generation of a number of secondary generators, and induced currents individually utilised for the production of light, and that if a person wanted to use the alleged invention of the patentees in connection with lamps of the kind described in the publication referred to, he would have to use generators similar to those used by Jablochkoff. Other anticipations were also put to Dr. Hopkinson, in all of which he admitted that there was a distribution of electricity by alternating currents and secondary generators. The distinctions he drew between such proposals and that of the patentees turned chiefly on questions of disadvantage in the special forms of secondary generators described in such anticipations, leading to more or less want of economy in the result; but he admitted that there was no novelty in the secondary generators described in the patent, and that they were no more economical or more suitable for the purpose of distribution than secondary generators of ordinary construction in use at the time, and that it was common knowledge to adopt such generators to produce any desired tension in the secondary circuits. The principal witness called on behalf of the petitioner was Sir W. Thomson. He gave evidence to a like effect with Dr. Hopkinson on the point that the specification gave no description of any special kind of generator to which the invention was limited, and further, that the generators described possessed no novel or patentable features, and did not differ from ordinary generators well known at the time. He further gave evidence that the system of distribution claimed was not novel, but that the anticipations set out in the particulars of objection, that more particularly of Jablochkoff, Edwards and Normanby, and Imray, completely anticipated the alleged invention of the patentees. Mr. Justice Kekewich ordered the revocation of the patent; and in the Court of Appeal, Lords Justices Cotton, Lindley, and Lopes, affirmed that decision. He (the learned counsel) submitted that the alleged invention in respect of which the letters patent were granted, was an invention never in fact made by the patentees, but was an impossibility; that the complete specification, as finally amended, described and claimed an alleged invention larger than, and different from, that originally claimed by the patentees, and for which the patent was originally granted; that the patentees failed to inform the public in their complete specification in what their alleged invention consisted, and how the same was to be performed, and had not enabled the public to ascertain what was the invention claimed by them, or how the same was to be carried into effect; that the alleged invention was not novel; that if the alleged invention was to be held to be restricted in any of the modes contended for at various times on behalf of the appellants, such restrictions did not constitute good subject matter for a patent, and did not constitute a patentable invention, and that, therefore, the appeal ought to be dismissed.

At the conclusion of the arguments,

Their LORDSHIPS said they were of opinion that the decisions of the Courts below were correct; and, therefore, they dismissed the appeal, with costs.

Judgment below affirmed, and appeal dismissed, with costs, accordingly.

Edison and Swan Company and Others v. Bayley Bros.

In the High Court of Justice (Chancery Division) on the 26th inst., the case of the Edison and Swan Company v. Bayley Bros. was before Mr. Justice Stirling.

Mr. ASTON said that it had now been arranged between the parties that the defendants should submit to a perpetual injunction, pay the costs, and take a licence.

Mr. LEVETT: I appear for the defendants, my lord, and I cannot say that the particulars are unreasonable.

Mr. Justice STIRLING: Very well, then; take it by consent.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 18, 1890.

Patent Litigation.—A legal difficulty seems to have arisen between the Thomson-Houston and Westinghouse Companies. The former, as controlling the Brush interests, have brought a suit against the Westinghouse Company for using the double carbon arc lamp, which is protected by the Brush patents. The Westinghouse Company, by way of returning the compliment, have instituted proceedings against the Thomson-Houston Company for employing the overhead construction for electric railroads, said to be controlled by a patent owned by the Westinghouse Company, and also for using the carbon brush, infringing the Forbes patent. What will be the outcome of this group of suits cannot now be predicted; but, if the Westinghouse Company presses the claims above mentioned, there is likely to be some trouble in electric railroad circles.

The Gas Commission.—There is the usual difficulty between the electric lighting companies and the Gas Commission in New

Digitized by Google

York city. The bids for city lighting, made by the companies some months ago, were, it will be remembered, refused, and new bids were called for. These have been now received, and prove to be substantially identical with the old bids; consequently, the Gas Commission makes the customary threats of going back to gas lighting.

The Westinghouse Electric Railway Company.—This new Company is rapidly getting ready for operations. One or two of its cars have been run in an experimental way for some little time past. The motors are said to be particularly well designed mechanically, and the running gear of the cars contains various important improvements. The whole system will doubtless be made public in a short time.

Tramways with Accumulators.—Two new systems have been brought to the public attention, each of them embodying some special design in motors and driving gear, but neither having made radical improvements in the matter of batteries. The United Electric Traction Company has done a little towards increasing the use of storage battery cars on the surface roads; and while there is a good deal of experimental activity, so far as the public is concerned, the matter seems to be at a standstill. The overhead system, of course, never can find its way into New York City, and indeed provokes a good deal of unfavourable comment wherever it has been tried in very populous districts, although the popular apprehension of it is entirely out of proportion with the real danger. Several other storage systems are in process of development, and among them all it is possible that this city may see something done towards surface rapid transit; but, meanwhile, some of the lines will probably be cabled, which means delaying the use of electricity for a considerable time, so far as that part of the city is concerned.

CORRESPONDENCE.

PROVING OHM'S LAW.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret that while making his useful suggestion calling attention to the fact that in iron and bismuth the resistance *must* be a function of the current, because of the effect of cross magnetism on their conductivity, Professor Silvanus Thompson should have gone out of his way to raise that wretched ghost of a student's difficulty concerning the statement of Ohm's law. To begin by defining resistance, and then to call "$C = \frac{E}{R}$" Ohm's law, is ridiculous, and worthy only of an archaic type of text book.

I had hoped that all chief teachers nowadays taught the law as follows:—That in a given conductor in a given state, the rates of the resultant E.M.F. acting in it, the current thereby produced is constant, however much the intensity of the current be varied; in other words, calling the ratio "resistance," that resistance is not a function of current intensity.

OLIVER J. LODGE.

LEAKS ON ELECTRIC LIGHT CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice that in your issue of the 11th you ask for any evidence of charring from leaks in wooden casing of electric light wires.

A case occurred in an installation temporarily under my care about three years ago. I traced a leak on some branch wires to a place where the cable was laid in deal boxing, and then laid in concrete, 6in. deep.

On cutting the concrete away I found the boxing saturated with water, and at a place where the boxing dipped an inch quite a pool of water collected. Just by this pool, but not quite in it, was a very badly insulated joint or negative pole, covered with india-rubber tape, but not jointed watertight.

Both the lid of the boxing and the insulation of the cable were charred away considerably, and the whole thing was hot when taken up. There was another leak on another main of the other pole.

The curious thing to me was the fact that the wood had evidently been a sponge to the concrete moisture, and absorbed all water near enough to be taken up, and then, owing to the concrete setting, had to retain it.

I enclose name of place and contractors, which you will see are both well known. I must ask you, however, to treat these names as confidential.—Yours, &c., J. SAYERS.

Telegraph Department, Midland Railway,
Derby, July 26, 1890.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. John Verity's letter *re* the installing of houses for electric light appears at a time when the necessity for uniformity of opinion as regards the fundamental points of importance in regard to this subject must be manifest to all those connected with electric light work.

There can be no doubt that differences of opinion as to the best ways of carrying out certain works must exist, as works have to be carried out under circumstances which vary with the numberless conditions obtaining in the individual cases, and it is the duty of the consulting engineer to specify under what circumstances and conditions the quality of the work should be increased or may be diminished and to what extent.

It is evident that Mr. Verity's letter bears upon another matter which requires consideration, namely, on the question of the real position of a consulting engineer, and in how far—if at all—he may be commercially interested in the work on which he advises and which he undertakes to superintend; but leaving this matter for the present out of consideration, it must be evident that there are right ways and wrong ways of wiring houses; this has been amply verified by experience of successes and of failures, and there can surely be no doubt at the present moment in the mind of any intelligent and unbiassed engineer as to what constitutes a safe installation for electric lighting.

Engineers are hampered in their specifications and contractors are worried beyond all endurance by the thousand and one petty differences of opinions existing among the inspectors of the various fire offices. The first attribute of a specification should be its definiteness; but under existing circumstances it is impossible for any engineer to draw up a specification without the introduction of some saving clause which shall provide for the fads of the various inspectors whose opinions on points of quite secondary importance have to be consulted.

I can only say in conclusion, that I trust Mr. Verity's letter may be the means of rousing such discussion of the relative merit of the various clauses in the existing fire rules as to lead to the adoption of a set of rules dealing with the main points of importance in the matter, and thus reducing this vexed question to a matter of comparative simplicity.—Yours, &c.,

ED. C. DE SEGUNDO.

Westminster Chambers, 7, Victoria-street, Westminster, S.W.,
London, 25th July, 1890.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Metropolitan Asylums Board invite tenders for the establishment of telephonic communication between the Schools and Pavilions for Imbeciles at Darenth, near Dartford. Full particulars may be obtained, and plan inspected, at the chief offices of the Board, Norfolk House, Norfolk-street, Strand, W.C., where sealed tenders, addressed to Mr. W. F. Jebb, clerk, and endorsed "Tender for the Establishment of Telephonic Communication at Darenth," are to be delivered by August 25th.

THE LIGHTING OF DUNDALK.—We are informed that none of the tenders received for the public lighting of Dundalk have been accepted.

MESSRS. SWINBURNE AND CO.—Messrs. Swinburne and Co. announce that they have completed the extension of their works

Digitized by Google

and machinery at Teddington, and that they can now guarantee the prompt delivery of Hedgehog Transformers. They also direct attention to their revised price lists.

THE PLANET ELECTRICAL ENGINEERING COMPANY.—This Company intimate that they require agents for their arc lamps in all the important towns of Great Britain.

PARTNERSHIP DISSOLVED.—The partnership between William David Ramsay and Cecil Walker, carrying on business as electrical engineers at 1, Princes-mansions, Victoria-street, Westminster, S.W., has been dissolved.

ST. MORITZBAD.—Messrs. Ganz and Co. will supply the alternators and transformers for the central station at this town.

ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT.—The *Elektrotechnischer Anzeiger* announces that this Company has decided on the purchase of shares in the Deutsche Lokal und Strassenbahn Gesellschaft to the value of 1,400,000 marks (£70,000), in order to be in a position to devote more energy to the introduction of electric traction.

MESSRS. MULLER AND EINBECK.—These well-known makers of the Tudor Accumulator at Hagen, Westphalia, have just turned their firm into a company, under the title of "Akkumulatorenfabrik Aktiengesellschaft," with a capital of 4½ million marks.

COMPANIES' MEETINGS & REPORTS.

The Direct United States' Cable Company (Limited).

The twenty-sixth ordinary general meeting of this Company was held at Winchester House, Old Broad-street., on July 25th, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. T. Finnis) read the notice convening the meeting and the minutes of the previous meeting, which were approved and signed as correctly entered.

The Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—I beg now to move the following resolution before I make the remarks which I usually do at these meetings:—

"*That the report of the Directors, dated July* 11, 1890, *together with the statement of accounts to June* 30, 1890, *annexed thereto, be, and the same are, hereby received and adopted, and that a final dividend be now declared of 3s. 6d. per share, free of income tax, making, with the interim dividends already paid a total dividend of 3½ per cent. for the year ended June* 30, 1890."

Before I ask you to approve of this resolution I shall, as usual, give you some particulars of the working of the Company's system during the last six months. The revenue for the half-year to 30th June, after deducting outpayments, amounted to £40,017 and the working and other expenses, including income-tax, but exclusive of cost of repairs, absorbed £17,616, leaving a balance of £22,401 as the net profit of the half-year, making with £8,318 brought from the previous half-year, a total of £30,719 which has been appropriated as follows:—Interim dividend of 3s. 6d. per share for the quarter to 31st March £10,624. 5s., proposed final dividend of 3s. 6d. per share for the quarter to 30th June £10,624. 5s., transferred to reserve fund account £8,502, balance proposed to be carried forward £968; total, £30,719. The revenue during the earlier portion of the half-year showed some falling off as compared with that of the corresponding period (the tariff being 1s. in each period), but in the later months an increase took place which more than recouped the previous falling off, the result on the whole showing a small increase of £390. The expenses in London, as shown by Abstract "A" in the accounts, remain practically the same as in 1889, with the one exception of stationery and advertising, which shows an increase of £67, due to extra tariffs and other stationery used in the competition for business. The expenses at Stations, as shown by Abstract "B" are on the whole £1,345 higher than those of the corresponding period of the previous year. This increase, as explained in paragraph 6 of the Directors' report, is due to the fact that the expenses of the Chief Office at New York (formerly a joint office) have now to be paid entirely by this Company. Looking to the active competition now going on in New York, the maintenance of an independent office by this Company in that City is considered important. A new station opened by the Company at Glasgow has been working since February last. The aggregate expenses which, but for the facts above mentioned, would have shown a reduction, are on the whole £940 higher than those of the corresponding period of the previous year. The reserve fund after being debited with £4,919 for cost of repairs, and credited with £4,390 for interest, &c., on the investments, and £8,502 transferred from the revenue accounts now amounts to £250,000. The investments, as heretofore, continue to be worth much more than the figure of cost at which they stand in the balance sheet. It will be in your recollection, gentlemen, that at the last half-yearly meeting I gave you a very full exposition of the position of the Company. I then stated that six months hence I feared it would be necessary to draw special attention to our reserve fund. We had been, during the active competition, drawing upon that reserve fund to some extent to supplement our dividends and to maintain the 3½ per cent. which we should otherwise have been unable to pay at the 6d. tariff. I now find, however, that it will not be necessary for me to appeal in any way to the shareholders to-day as to our reserve fund. It seems to me that we have turned the corner. We have for the first time during the last two or three years been adding to instead of taking from the reserve fund. We have increased it now to a very nice round sum; but still I hope, adopting the principle which we have laid down of putting the interest to the reserve fund, and such a sum as we can conveniently spare from our income, that we should continue to increase that reserve fund so as to place ourselves in a thoroughly independent position. I believe our cable stands at a cost very much lower than that of any other cable in the Atlantic at the present time; and when we take into consideration our large reserve fund, I think there is no company which can compare with us as to the value of our property because we consider that our cable, which stands at a comparatively small price to-day, is just as good as any that lies in the Atlantic at the present time, and the others stand at two or three times a higher price than ours. Our cable is now in good working order—so good, in fact, that we are able to work the duplex system by it. In other words, it gives us practically the advantage of two cables; and I am very pleased to say that we are doing our full share of the pool traffic over the Atlantic at the present time. I am bound to say that, working as the "pool" does now, there is an impression abroad that a single cable is a very dangerous investment. But when I tell the shareholders of the Direct Company that ours is one of seven cables in the Atlantic you will feel that your position is a safe one. If our cable were broken for twelve months it would not interfere in the least degree with our income, and the other cables are quite equal to carrying the traffic. If our cable were broken for two years we would still have an income, and if it were broken for three years we would still have a small income. Therefore I wish it to be understood, as many appear to have forgotten the fact, that though we stand as a single cable, we are guaranteed by six other cables. That is a very strong position which we occupy, and taking that in connection with our reserve fund I look on the Direct Company as possessing now the cheapest cable in the Atlantic. We had broken cables the other day, and it is very difficult to effect repairs under £5,000; but we find that these breaks have not taken place from any real decay of the cable, but have arisen from the anchors of fishing boats. The fishermen drop their anchors when fishing and when they take them up again they sometimes pick up our cable. We have done all we can to induce them to drop it when they pick it up, having even undertaken to provide them with new gear if they do so. We have found a feeling of justice towards us at the hands of the fishermen, who have also shown a disposition to save us from any unnecessary expense. I am pleased to be able to make this statement about our cable because people have said to me, "But your cable is only a single cable; it is no good." However, as I have just said, if we have a single cable we are guaranteed by six others. There is another thing in regard to our policy. When we have had a break, we have never hesitated, whatever the weather was, to send out a ship to make the repairs and we have been singularly fortunate in having our repairs promptly executed. We consider that it is a duty to the joint purse—to the "pool" in which we are taking part—to do as fully and fairly our share of the work as we can, and I believe at the present moment we are doing our fair proportion of it. I think it is encouraging, though it is not so encouraging as I should desire, that at the present moment at the 1s. tariff we are carrying quite as many messages as we did at the 6d. tariff. But still, we are not getting that amount of money which such a property is entitled to; and therefore I still hope that something will occur, either by effecting economies through our instruments or our working combination, by which we may see our dividend larger than it is now; but the real point is that, at the present moment, there are more cables in the Atlantic than are required for the existing traffic. We must try, however, to work it out in some way or another—I am not just now prepared to say how—but I say this that this submarine system of telegraphy is a magnificent property. It has become a necessity for the world to have these cables efficiently and properly worked; and I think it would be a reflection upon all concerned if we did not manage in some way to give a fair return to our shareholders, for what has become a great commercial and political necessity. These are my own private views on the subject; and as long as I am connected with the submarine telegraph system I shall always bear in mind, that while we are doing the public a very great benefit, we must be just as well as generous, and must look to our shareholders at the same time. I may say that the position of the "pool" is probably stronger now than it has been for a considerable time. Mr. Ford and myself have just lately been attending the telegraph conference in Paris, and I am very pleased to say that while our cables did not come very much under consideration, the little that did was fairly considered by the other companies, and settled upon a basis which I think ought to be satisfactory to all parties concerned. The interests of the Company were very carefully attended to; and when I tell you that the results were very satisfactory to your Board, you will understand that we have lost nothing by the Conference. I think, gentlemen, these are pretty much all the remarks I have to make to-day, and I will close them by saying that I should be better pleased if we could pay you the old 5 per cent. instead of the 3½ per cent. which we offer you to-day; and if it is possible to work the concern up to that figure, I think you may depend upon your Board giving it every consideration in their power. I now beg to propose the resolution which I have already read to you.

Mr. WM. FORD seconded the resolution, which was carried unanimously.

The CHAIRMAN moved and Mr. FORD seconded the next resolution as follows:—

"*That Mr. Charles Meara be, and he is hereby, re-elected a Director of this Company.*"

The resolution was carried unanimously.

On the motion of the CHAIRMAN, seconded by Admiral R. C. MAYNE, C.B., M.P., the following resolution was carried unanimously:—

"*That Mr. Emmanuel Maguire Underdown, Q.C., be, and he is hereby, re-elected a Director of this Company.*"

Mr. W. J. DEY proposed and Mr. GRIFFITH seconded the next resolution, as follows:—

Digitized by Google

"*That Messrs. John George Griffiths, F.C.A., and John Sawyer, F.C.A., be, and they are hereby, re-elected Auditors of this Company for the ensuing year, at a remuneration of* £50 *each.*"

The motion having been agreed to *nem. con.*,

The CHAIRMAN said: That concludes the business of the meeting. I think we may be considered in a very satisfactory state by our shareholders, seeing that we have such a small attendance—I think the smallest attendance I ever remember at a meeting of this Company.

Mr. GRIFFITH proposed a vote of thanks to the Chairman and Directors, and made a touching allusion to the death of Lady Pender, who, he said, was beloved by all who knew her.

Mr. JACKSON seconded the motion, which was carried unanimously.

The CHAIRMAN briefly acknowledged the vote, and the proceedings terminated.

Globe Telegraph and Trust Company (Limited).

The seventeenth ordinary general meeting of the Globe Telegraph and Trust Company (Limited) was held on Tuesday last at Winchester House, 50, Old Broad-street, E.C., under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. W. Payton) read the notice convening the meeting, and the minutes of the previous meeting.

The report of the Directors was taken as read.

The CHAIRMAN: Before asking you to approve of the report, I will, as usual, make a few remarks. The report, as you will observe, is very full. It gives the history of the transactions of the Company during the past year, and contains a tabulated statement of our investments, their cost, and the return on their cost, and the exact amount of the dividend received. In looking over the remarks I made when I had the pleasure of addressing you a year go, I find that were I to repeat them to-day they would be quite appropriate to our proceedings now. I indicated then that there was a considerable amount of prosperity prevailing in the submarine telegraph system generally. We had terminated our battle in the Atlantic, and we found that we were receiving as many messages at the 1s. tariff as we had previously been receiving at the 6d. rate. That was all very satisfactory, and contributed, of course, materially to our exchequer, and eventually, as I shall show you to-day, to our dividend. During the last three years we have been steadily progressing; but, as you know, we progress just as the submarine companies progress, and to-day we are, upon the whole, in a very satisfactory position; and we propose to pay you, as I foreshadowed at the last meeting, a net dividend of 5 per cent. upon the ordinary shares, against £4. 12s. 6d. per cent. which we paid on the last occasion. We have received during the last financial year £198,466. After deducting working expenses we have a balance of £193,499, of which we have distributed £130,806, leaving an available balance for our final dividend of £64,700 to-day. We therefore recommend a dividend of 3s. on the Preference shares and 4s. 3d. on the ordinary shares, which gives 5 per cent. on the latter as against £4 12s. 6d. per cent. paid last year. This, I think, will be satisfactory to the body of our shareholders. We shall carry a small balance forward, but this being a Trust Company we are not intending to put any large amount to reserve. If we take the combined dividends of the Preference and ordinary shares during the seventeen years of the existence of this Company, we find that we have paid an average dividend of £4. 6s. per cent. The dividend we pay to-day makes 5 per cent. for the year, which is a gratifying circumstance, and we hope we may retain the level which this year has given us. With respect to the Companies in which we are largely interested, such as the Eastern and Eastern Extension, it may be said that the result of the Paris Conference has not been unfavourable as regards our Company. I may mention that the policy of these Companies is a very broad one. Their object is not only to do their work well, but to satisfy their customers and the general telegraphing public. Telegraphs have become a great necessity—in fact, the world could not now go on without them, and as we are the head of that great system, it is our business and duty to do our work in such a way that no fault can be found with us. You have read a great deal about the Imperial British East African Company. They had a meeting the other day in London, at which they gave an idea of what they are doing. Unfortunately, they overlooked saying that the Eastern Company at their own cost had laid down a cable to connect their important port of Mombassa with the more important port of Zanzibar. That was done entirely at the cost of the Eastern Company and entirely in the interests of the East African Company. As I have said before, the policy of these submarine Companies has generally been to follow the flag—to follow the trade, and wherever we find trade and civilisation we go alongside of them so as to help them. Gentlemen, the changes in the past half-year have been very few, and the Conference at Paris will not, I think, in any material way disturb the existing state of things. One of the Companies—the Eastern Extension—has entered into an arrangement with the Australian Governments to make a very bold and a very grand experiment—that is, to reduce the tariff from 9s. 4d. to 4s. That is done by the Governments of the Colonies guaranteeing the Companies 50 per cent. of any loss that may accrue. The Directors of these Companies are so confident that the reduced rate will double the traffic that they have not hesitated in taking their part of the risk. I mention that in confirmation of the former remark I made that the policy of these Companies is broad, and the broader it is the more prosperous it seems to me they will be; and as we in this Company are dependent on the success and prosperity of these companies, I think we may look on with perfect confidence that what they do will materially benefit the Globe Company. The changes in our investments last year were very few. We acquired 350 more shares in the American Cable Company, which are guaranteed by the Western Union, and we have acquired them at a price which gives a good return. The shares are guaranteed by the Company for 50 years, and after that period they are to return the cable in as good order as when they took it in hand. I only wish that I might be alive to see the cable that is taken over. The German Government have taken over all the interest in the German Union shares which have disappeared from our statement of assets. There only remains the German-Norwegian Line, and this no doubt will ultimately be acquired by the German Government. I think altogether it would require a little ingenuity on my part to make any statement of sufficient importance to extend my speech. I have given you, I hope, in a few words, evidence that everything is going on as satisfactorily as possible, and I hope, if I have the pleasure and the honour of meeting you next year, that I shall be able to show you that the progress which has been made since last year still continues. Before I close my remarks I wish to allude to the loss of one of our Directors, Sir Daniel Gooch. He was a man well-known in public life as an able administrator, and one in whom the public generally had confidence. In losing Sir Daniel Gooch we have lost a wise counsellor, and I desire publicly to express our regret at that loss. The world moves, changes are continually taking place, and somehow or other men come in to take the places of those who have gone before. I hope the undertaking, when well established, will continue to prosper even when those who projected it have passed away. I now beg to move:—

"*That the report and accounts for the year ended July* 18, 1890, *submitted to this meeting be, and they are hereby, received and adopted, and that a dividend be now declared, payable on and after this date, of 3s. per share on the Preference shares, less tax; and of 4s. 3d. per share on the ordinary shares, income tax having already been deducted, making, with previous payments, a total dividend for the year of* 6 *per cent. on the Preference shares, less income tax, and of* 5 *per cent. net on the ordinary shares.*"

The MARQUIS of TWEEDDALE seconded the motion, which was agreed to unanimously without discussion.

In answer to Dr. POCOCK,

The CHAIRMAN said: The East African Company have their headquarters at Mombassa, about 140 miles from Zanzibar. They are making that an important post; and the Eastern Company, over which I preside, thought that the best way they could help on that great enterprise and the development of Africa, was by laying down a cable from Zanzibar to Mombassa. That we did entirely at the cost of the Eastern Company, and we trust that the traffic will be such as to repay us for the outlay. At all events, we have done that which we considered it our duty to do—to follow the flag and to encourage as far as lay in our power the development of the country. We have found in the past that telegraphs have played an important part, and we shall continue the policy we have pursued whenever we can do it with effect. He then proposed the re-election of Mr. William Ford as a Director of the Company.

Sir JAMES ANDERSON seconded the resolution, which was carried unanimously.

The CHAIRMAN then proposed the re-election of Sir Henry Daniel Gooch, Bart., as a Director, observing that that gentleman was a son of the late Sir Daniel. The Directors thought that whenever there was evidence of ability, and where the father had done good work, it was proper that the son should succeed to his position.

The MARQUIS of TWEEDDALE seconded the resolution, which was carried unanimously.

On the motion of a SHAREHOLDER, seconded by Dr. POCOCK, the auditors, Mr. John George Griffiths, F.C.A. (of the firm of Messrs. Deloitte, Dever, Griffiths, and Co.), and Mr. Wm. Griffith, B.A., were re-elected auditors of the Company.

Mr. WILLIAM GRIFFITH said that he felt very grateful for this renewed vote and this expression of their confidence. It was not only a duty but a pleasure to audit the books of the Company. The book-keeping was excellent. They had not merely examined the books but the vouchers as well, and had looked at the securities, which were all found safe. He thought they might not only congratulate themselves on the larger dividend that had been declared, but on the future which Sir John Pender hoped would come to them, and of which they had every assurance. The present was one of the largest dividends they had ever received, and must be a cause of congratulation. But while they congratulated themselves on this success he thought they must agree with the early remarks of Sir John Pender in reference to the loss they had sustained by the death of one of their old Directors—one who had been connected with them for so many years—Sir Daniel Gooch, who had the confidence of every one who knew him. He (Mr. Griffith) had met him frequently at the meetings of the Great Western Company, and in all respects he was a man of mark. He hoped that the Chairman's remarks in reference to the successor to Sir Daniel Gooch, who had been elected to-day, would be realised; but while touching on this subject, they ought to remember that they had not only lost one of their Directors, but that one of the Directors had had his home darkened by the loss of an admirable and estimable wife—one who shed a glamour over his home, who administered its hospitality, and who was admired not only for her hospitality, but also for the advice which she was in the habit of giving to her very able husband, Sir John Pender, who, he hoped, would excuse him for making these remarks on such an occasion. It was true that his home had been darkened, but they knew that there was a brighter home above, whose foundations were indestructible, whose happiness was without alloy, and whose duration was not merely temporary. He thought they would agree with him that they ought not only to express their gratitude to Sir John Pender for his able administration of the Company's affairs, but their sincere regret at the loss which he had sustained.

Mr. JOHN NEWTON, in seconding the resolution, said he did not think it was an occasion when they could say many words, but what the previous speaker had observed so truly represented the sympathetic feeling of the shareholders in the Globe Company for Sir John Pender that he felt sure it would receive the support of the meeting.

Digitized by Google

The CHAIRMAN: Ladies and gentlemen,—It is a very pleasant state of things between Directors and a body of shareholders when, after 17 years' experience and trial, those shareholders are able to express the kind and warm sympathy which you have done to-day. I think it is an evidence that, apart from the general conduct of affairs, which has secured for the Board your confidence, there is something beyond that circumstance when we secure from you your sympathy. I thank Mr. Griffith most warmly for the kind way in which this vote has been proposed by him, and I also thank Mr. Newton for the very sympathetic manner in which he has seconded it, as well as the shareholders for the cordial way in which it has been received. Mr. Newton, I believe, has attended almost every meeting out of the 17 which we have held, and he has seen the progress of this concern, and more or less taken a part in it. We are to-day a very sympathetic body of shareholders and Directors, and I thank you very much for your kind expressions.

The proceedings then terminated.

The Telephone Company of Austria (Limited).

The seventh ordinary general meeting of this Company was held yesterday at the offices, 53, New Broad-street, under the presidency of Mr. Henry Grewing.

The SECRETARY (Mr. Richard Rodgers) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—I have very little to add on this occasion to the observations which are contained in the report which has been issued, as the Company has been progressing very satisfactorily during the last financial year. The increase, as you will have noticed, amounts to rather more than it did at the corresponding period of the previous twelve months, when it was 20,749 florins, it being now 27,450 florins. Since the date of our financial year to 31st of March, a satisfactory increase has taken place, amounting to about 17,430 florins, which, of course, will appear in the next accounts. I have to congratulate the shareholders on the fact that this is the first year since the existence of the Company that we have been in a position to declare a dividend on the ordinary shares, 2½ per cent. having been paid already and 1½ per cent. being proposed to be added to that, making a total of 4 per cent. for the year. It was not that we had no profits to apply to dividend on previous occasions; but, as you are all aware, the demands on capital have been so pressing that it was not so easy for us to satisfy capital account requirements. We had, therefore, to invest surplus profits in the extension of the business, and there is no doubt that we shall now begin to reap the benfit of this policy. I may say that the Consolidated Company have made certain arrangements by which they are prepared to supply us with any reasonable amount of capital so long as we can show that it is judiciously invested. Both as regards revenue and net profits, our permanent prosperity depends on a continuation of our concessions with the Austrian Government. They will expire between this and 1893; and we are now in negotiation with the Government for a prolongation of them on the basis of certain understandings which were arrived at between ourselves and the Minister of Commerce as to the time of the prolongation or the purchase. We have no doubt that it will be a satisfactory arrangement for the future stability of the Company. The Chairman concluded by moving the adoption of the report and accounts and the declaration of the dividend recommended.

Mr. C. L. W. FITZGERALD seconded the resolution, which was carried unanimously.

The retiring Director, Mr. R. E. Bateman, was re-elected to his seat at the Board; and the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., having been reappointed, the proceedings terminated.

The Edison-Swan United Electric Light Company (Limited).

The seventh annual ordinary general meeting of the shareholders of this Company was held on Monday at the Cannon-street Hotel; Mr. James Staats Forbes presiding.

The SECRETARY and MANAGER (Major S. Flood Page) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said that the report was one of the most embarrassing he had ever had to deal with—it did not want any apology. In fact, he was scarcely at home with this sort of thing, particularly in the Edison and Swan Company, because they were old enough to remember when the meetings were not of the present character, and the results were not quite so satisfactory. However, they would take it for what is was worth, and as good wine needed no bush he would have very little to say about it. The report itself was so exceedingly brief as to indicate that there was not much to be said. The facts were to be found chiefly in the figures, in connection with which the important fact was the profit and loss account, and the chief feature of that was that the balance carried to the credit of that account, after making every fair and proper charge against it for the working expenses of the undertaking and for the due depreciation of plant, &c., presented the respectable balance of £61,115, enabling the Company to divide, on the recommendation of the Directors, if the shareholders should see fit to approve it, the full 7 per cent. upon the capital, and a very considerable contribution in respect of those sadly too long years when there was no dividend to pay at all. They all knew that the dividend on the ordinary stock to the extent of 7 per cent. per annum was cumulative—that was to say that, in the years when it was not secured by the profits, any balance was carried forward as a claim on the future. Having waited for a great many years for the happy event, they had been last year able to wipe out some of those arrears, and they would be able to do so in a larger proportion this year. They would see that stock on hand on July 1, 1889, was £25,985. He might remind honourable proprietors that the character of the business demanded a very large amount of capital being locked up in stock. The lamps, as was well known, were of a very great variety of form and power, and many people had different ideas as to what kind they would like, and in order to be ready to supply whatever was wanted they must keep a very large stock on hand in anticipation of the demand. If they would cast their eye to the opposite side of the account—for he might as well exhaust the question of stock at once—they would find that there was a large increase, by the sale of lamps, fittings, &c., from £25,985 to £56,266. He would relieve their minds at once by saying that only a small portion of this increase was attributable to the number of lamps, which had kept pace in almost arithmetical proportion with the number of sales. A large portion of this increase was the price of obtaining platinum, which, with a certain amount of foresight, they had availed themselves of the opportunity of buying at prices which were already considerably exceeded, and that platinum was carried to the account at cost price, and was held in reserve, and would account for £21,000 of the increase. They found that in the market the supply of it did not keep pace with the increased demand, and putting two and two together, they considered that the price might go up, and, therefore, they laid their hands on a considerable amount of it. Wages, purchases, &c., amounted to £73,719; then there was the cost of conducting the business, salaries, Directors' fees, rent, office expenses, &c., £13,915, and depreciation on plant £1,838. On the other side of the account, as he had said, by sale of lamps, fittings, &c., they had realised £61,865, while by interest on investments they had earned £1,442. Stock in hand stood at £56,266. The difference between the sales and interest and the value of the stock, and the value of the stock on the other side, plus the expense of the year's business, left a balance of £61,115. By reference to the accounts it would be seen what they proposed to do with this amount, namely, to pay a dividend for the year ending June 30, 1890, at 7 per cent. per annum (of which £12,371. 14s. 7d. was paid as interim dividend, on February 20, 1890, being £24,743. 9s. 2d.; and also the payment of the balance of cumulative preferential dividend on the "A" shares, for the year ended June 30, 1884, at the rate of 4 per cent., which would amount to £14,139. 2s. 4d.; and payment on account of cumulative preferential dividend on the "A" shares at the rate of 4 per cent. for the year ended June 30, 1885, £14,139. 2s. 4d. This meant that for the year ended June 30th, 1884, they last year paid 3 per cent., which left a balance of 4 per cent. in arrear, and for the following year they now purposed paying 4 per cent. Having done that, they still had £3,093, which they had carried to reserve fund. Coming to the share capital account—or the balance-sheet—there was no substantial alteration. The capital remained exactly as it was in the last account. The only figure which would be affected would be the one under the title of "B" shares, which were entitled to one-fourth of the profits after a cumulative preferential dividend of 7 per cent. per annum had been paid on the "A" shares. The particular part of that entry was that Preferential Cumulative dividend of 7 per cent. amounted on June 30, 1890, to £110,769, which was the balance of the amount still to be wiped off out of future profits. Sundry credit balances and reserve fund amounted respectively to £26,257 and £4,595. On the other side of the account they came to what they got for that capital—by cost of patents, goodwill, preliminary outlay, loss on working, &c., as per last balance-sheet—£235,614, that had been from time to time subjected to diminution by writing down on the realisation of property and so forth. There was a further expenditure thereon during the year of £2,439, making £238,053. As a set off against this, there followed an item—"Less amount realised by sale of plant, &c."—amounting to £2,030, bringing the figure down to £236,022. The amount of "B" shares of the Company issued as *per contra* was £117,820. They knew the history of these shares. They were given to Mr. Edison and his friends as the value of their interest in the concern. Their other assets were: Manchester Edison-Swan Company (Limited), £100,000, "B" shares at nominal cost £12,000; freehold property, £33,306; plant and stock, £77,221; office furniture, £256; debtors, £15,203; investments, £27,500; and cash at bankers and in hand, £31,563. They would see that not an inconsiderable amount of the capital of the Company was in the shape of solid pudding, namely, freehold property, £33,306, which was the property of a going concern, embracing the factory at Ponder's End, which they had bought cheaply, and on which they had spent some money, and which from time to time was being extended in order to meet the very great demand possibly for the lamps in the future. They put its value down at what he thought was a very safe figure. The same might be said of the other investments. Unless they wished him to go into any details he thought it would be wise to end what he had said by commending to them the recommendation of the Board to disburse the proposed dividend, giving them the assurance that in the details of the several amounts a very liberal allowance had been made on all heads on the debit side, and the balance which was brought forward was one which was absolutely without charge upon it which the current revenue ought to bear. He concluded by moving:—

"*That the report and accounts to June* 30, 1890, *be received and adopted.*"

The DEPUTY CHAIRMAN (Mr. F. R. Leyland) seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed, and the DEPUTY CHAIRMAN seconded the next resolution as follows:—

"*That a dividend at the rate of* 7 *per cent. per annum be and is hereby declared on the A shares of the Company for the half year ending* 30*th June,* 1890 (*making* 7 *per cent. for the year*), *and of* 4 *per cent. in completion*

Digitized by Google

of payment of arrears of Cumulated Preference Dividend for the year ending 30th June, 1884, and of 4 per cent. in respect of arrears of Cumulative Preference Dividend for the year ended 30th June, 1885; all to be distributed in accordance with the provisions of Clause 87 of the Articles of Association."

On the motion of the CHAIRMAN, seconded by Mr. WILSON, Mr. Shelford Bidwell, F.R.S., was elected to a seat at the Board.

On the motion of Mr. DONOVAN, seconded by Mr. DAY, the Company's auditors, Messrs. Welton, Jones, and Co., were reappointed; and a vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

Manchester Edison-Swan Company (Limited).

The eighth annual meeting of this Company was held in the Memorial Hall, Albert-square, Manchester, on Monday; Mr. V. K. Armitage, Chairman of the Company, presiding.

In moving the adoption of the report and balance-sheet, the Chairman said they were not as satisfied as they might have been with the result of the year's operations, inasmuch as, instead of making something over 10 per cent., as they did in the previous year, they had only made about 5 per cent. That was owing to no fault of theirs, for they had worked as hard, if not harder, for the 5 per cent. than they did for the 10 per cent.; but the real cause was that all over the country there was a falling off in the demand for small separate installations. Parliament had been issuing provisional orders for central stations broadcast, and people who wished to have the electric light were waiting to see what would be the outcome. The Directors knew a great many cases in which people put in the wires when building their houses or offices, but would not give the order for electric light installations and private plant because they hoped in a short time to be able to draw their supply from a central station in the same way as they now did gas. He believed this was the experience of every electric lighting company. He had not the smallest doubt that when the provisional orders were put into execution the Manchester Edison-Swan Company, with the name they had acquired for doing good work, would get a fair share of the work which he anticipated would have to be done. Since the last meeting Mr. J. R. Williamson had resigned through ill-health, and the Directors had appointed in his place Mr. W. P. James Fawcus, who had special knowledge of central lighting stations. The profit and loss account showed a falling off in the profits and an increase in the expenditure, the latter simply meaning that the more difficulty there had been to get orders the more money and time they had spent in trying to get them.

Mr. ISAAC CREWDSON WATERHOUSE seconded, and the motion was carried.

In answer to a question as to whether it would not be advisable to hold the meetings half-yearly instead of yearly, the CHAIRMAN said he did not think it was necessary.

On the motion of the CHAIRMAN, seconded by Mr. WATERHOUSE, it was agreed to appropriate £1,000 of the year's profit to the payment of dividend at 5 per cent. per annum, and it was also resolved to vote £150 of the balance (£647 6s.) as remuneration for the Directors.

Sir Joseph C. Lee and Mr. I. C. Waterhouse, the retiring Directors, were re-elected, and Messrs. Jones, Crewdson, and Youatt were also re-elected auditors.

A vote of thanks to the Chairman concluded the meeting.

The following is the Report of the Directors for the year ending May 31st referred to above. The net profit, including last year's balance, amounts to £1,647. 6s., which it is proposed to appropriate as follows:—

	£	s.	d.
To payment of dividend at 5 per cent. per annum ...	1,000	0	0
To balance carried forward	647	6	0
	£1,647	6	0

If the above be approved, the dividend warrants will be issued on August 1, 1890. Since the last meeting the Company's Managing Director, Mr. J. R. Williamson, has resigned through ill-health, and the Directors have appointed Mr. W. P. James Fawcus as manager. Two of the Directors, Sir Joseph C. Lee and I. C. Waterhouse, Esq., retire in accordance with the Company's Articles of Association; they are, however, eligible, and offer themselves for re-election.

Elmore's Patent Copper Depositing Company (Limited).

The first annual general meeting of this Company was held on Monday, at Cannon-street Hotel, E.C.; Mr. E. J. Carson presiding.

The SECRETARY (Mr. J. Shurmer) having read the notice convening the meeting,

The CHAIRMAN apologised for the absence of Sir John Morris (the Chairman of the Company) and said:—The Directors are very glad to be able to meet you to-day with what I will venture to call, taken on the whole, an excellent record of progress from the date of the formation of the Company, and substantial results in the shape of profits. The report and accounts which, I suppose, as usual, will be taken as having been read, show that we have made the large sum of £107,111 by the sale of the licence to manufacture wire. After writing off the original estimated value of this licence, and distributing the large amount of £35,000 among the shareholders, we have a balance brought forward from profit and loss account of nearly £40,000; and I venture to think that these are satisfactory results to have been obtained within the short space of time that the Company has been in existence. I am often met out of doors with the question, "Why have you not sooner commenced manufacturing work, and proved the commercial value of your process?" I am not going to excuse this delay, for I think I can justify our policy, and will prove to you that you are indebted for the very large profits which we have earned for you to the policy of the Board in changing the originally selected works at Sheffield, which has been the principal cause of the loss of time. Had we carried out the original intention of erecting our plant and machinery in these buildings, we should no doubt have got to work much quicker, but we soon discovered that our process was capable of very large developments and extensions in different directions, and that we should inevitably require a large amount of land adjoining the works of the original company for the purposes of the sub-companies which we soon foresaw it would be necessary to form, in order to extend our operations, as they will require to be extended. Land suitable for our purposes was not to be had in the neighbourhood of the factory first selected; and as it was of the first importance that any new works which might have to be erected for the extension of the process should be close to the parent company's works, in order that they might be managed under the supervision of the Messrs. Elmore, we set about looking for a more favourable site, which we eventually found in Haigh Park, close to Leeds, as you have already been told. There we have unlimited room for expansion, with the added advantages of cheap fuel and excellent means of communication, both by rail and canal, and at that place we have accordingly erected our works, and found a site for the first of our extensions, viz., the works of the Elmore Wire Company, and without this site we could not have ventured to bring out the Wire Company at the time we did, and with the very satisfactory results in the shape of profits with which you are all acquainted. Those who cavil at what they consider our long delay should consider that we have so thoroughly developed and proved our wire process as to completely gain the confidence of the trade—so much so, indeed, that the Wire Company has already contracted to sell the whole of its possible output of wire spirals for some time to come to a powerful group of Birmingham wire drawers, at prices that will not only show a very handsome profit to the shareholders of that Company, but which will also largely benefit ourselves as the sole owners of the founders' shares. The exhibition of our products, which is now on view in Queen Victoria-street, has proved to the trade that we can manufacture copper tubes on a commercial scale of any diameter, and of a quality that cannot be approached by any other process, with the result that we have not only received many inquiries and large orders for our manufactures, but also negotiations have been set on foot with the object of inducing us to grant licences to the trade to manufacture goods of certain classes for themselves. Here I may remark that there is room for all, and that the policy of your Board will be not to fight with the existing manufacturers, but to work in concert with them. There are plenty of articles which it will pay us well to allow the copper manufacturers to make for themselves by our process; while, on the other hand, there are other articles, such as tubes of large diameter, which it will pay them to hand over to us to manufacture for them. The most serious by far of the difficulties encountered, causing delay, was the failure of the first engine supplied to us. The Board spared neither pains nor expense in regard to the purchase of this engine. The manufacturing firm was one of recognised repute; nevertheless, the results were most unfortunate; and the makers, thoroughly alive to their responsibilities, are now engaged in substituting another new engine for the defective one. Meantime we have two other engines at work, and giving great satisfaction. The greater part of our preparations at Leeds are now completed; all that remains to be done is to finish and fit up the extensions of our depositing sheds. This work is comparatively easy, but we were resolved not to undertake it until we had gained not only practical experience with the first 5-ton a week plant, but also experience as to the requirements of the trade—a most important point, for on these requirements depended to a large extent not only the detailed arrangement, but also the leading dimensions of the large sheds. All this experience we have now gained, and we are proceeding as rapidly as possible with our extensions. As to the future, the Board entertains no feelings but those of confidence. Your sources of profits, as foreshadowed in the prospectus, come under two heads—viz., those derived from the manufacture of the specialties of the Company and those to be derived from the granting of licences to others. From the last of these sources you have already derived a large benefit, and during the current year and afterwards there is every reason to conclude that a very satisfactory income will be derived from granting licences to the large existing copper manufacturers. From the former source the profits are now beginning to accrue, and the results will go on continually increasing with the extension of your works. Your processes have been thoroughly proved, not only in a technical sense, but also commercially, and I therefore consider that we have every reason to look forward confidently to a long career of prosperity. I must not conclude without paying a tribute to the energy, talent, and industry of our works managers (the Messrs. Elmore); they have had an arduous task to accomplish, and have been unremitting in their endeavour to promote the prosperity of the undertaking. I now beg formally to move:—

"*That the Directors' reports and accounts for the period ending June 30th 1890, be received and adopted, and that a dividend of 25 per cent. upon the paid-up capital of the Company be, and the same is hereby, declared payable on the 30th instant.*"

Mr. F. L. RAWSON seconded the motion.

Mr. RUCKER asked whether the estimate given in the prospectus as to the cost of production had been verified, and whether there was a large amount of work offering at remunerative prices.

Mr. HURST wished to know whether the Board had considered the desirability of setting aside some portion of the large profits made last

Digitized by Google

year by the sale of their patents to create a reserve fund. It seemed to him that all businesses depending upon industrial inventions were subject to great vicissitudes, and, consequently, it was necessary to strengthen the hands of the Company by retaining for a period some portion of the proceeds which were now in hand. He also thought that the fees and bonus of the Board amounted to a large sum for a small Company like theirs. If part of the profits were set aside for creating a reserve fund, there would not, he said, be the large dividend paid to the shareholders or the large percentage of bonus paid to the Directors.

The CHAIRMAN pointed out that the £20,000, the estimated value of the patent for the manufacture of wire, had been placed to the reserve.

Some other questions having been asked, the CHAIRMAN replied, and then went through the various items in the accounts, concluding by saying:—I am happy to say that the cost of manufacture is considerably less than the estimate of the vendors. We have received a great many large orders, but we have not taken them because they are beyond our means of completing. They exceed the capacity of even our extended works. By refusing these orders do not understand that we are casting them adrift altogether. I think our position is such that we can at any time get any amount of work to keep us in full swing. With regard to the sale of licences and division of profits, we very properly took counsel's opinion on the subject before we acted, and our action is the result of their opinion.

In reply to a Shareholder, Mr. ELMORE said that he believed in six months from now they would be able to pay a dividend by manufacturing. They were actually earning money at the present moment from manufacturing.

After further discussion, Mr. HURST moved as an amendment:—

"*That the accounts be adjusted by the creation of a reserve fund to the extent of* £30,000, *and that the balance remaining thereafter be distributed in the form of a dividend to the shareholders.*"

The amendment having been seconded, was put to the meeting and rejected, and the motion for the adoption of the report carried with three dissentients.

The Board were then re-elected, and the auditors reappointed, after which a vote of thanks was accorded to the Chairman for presiding.

The following is an abstract of the Directors' report, &c., for the period from the date of the Company's formation on January 18, 1889, to June 30, 1890:—

In March last the Board disposed of the exclusive British licence for the manufacture of wire to Elmore's Wire Manufacturing Company (Limited). The shares of this Company (£2 each), were issued at a premium of £1, half of which, in addition to the sum of £75,000, went to our own Company. The issue was made to about 500 applicants. A total sum of £105,000 has been received from the Wire Company, and, in addition, our own Company has a further interest contingent upon the allotment later on of the balance of shares of the first issue. Our own Company holds, also, all the founders' shares, which are entitled to one-half the profits after 20 per cent. has been paid to the shareholders of the Wire Company. The Board regard these founders' shares as a most valuable asset. It may here be stated that the Wire Company have received an offer from a strong group of Birmingham firms to take their whole output of wire spirals at remunerative prices.

The Board recommend that out of the sums above mentioned an immediate distribution be made of 10s. per share, less income tax, which, with the interim dividend of similar amount paid in April last, makes a total distribution equal to 50 per cent. on the paid-up capital for the period named.

The sum of £20,000, being the estimated original value of the patents for the manufacture of wire, has been reserved, and will be invested or employed in the Company's business, as may be deemed most expedient.

A further amount of £4,584. 8s. 3d. is carried forward, after setting aside £35,000 for the second dividend referred to above.

After alluding to the acquisition of a new site for their works, and to the delay in commencing operations through the failure of the engines supplied, the Directors report that everything is proceeding satisfactorily at the works.

Of the 20-ton per week depositing plant, now in process of completion, the first section, capable of turning out five tons a week, has been satisfactorily at work for several weeks. The works are fitted with the electric light throughout, and an ample supply of copper purchased at prices considerably below the present market quotations have been provided.

The demand for the Company's products is far in excess of this 20-ton plant, and the prices obtainable are most remunerative, and the whole of the available plant is engaged in the execution of orders.

Cuba Submarine Telegraph Company (Limited).

Report of the Directors for the half-year ending 30th June, 1890, to be presented at the thirty-eighth ordinary general meeting of shareholders to be held on August 6th, 1890, at 12 noon.

The Directors beg to submit, duly audited, the balance-sheet and accounts for the half-year ended June 30th last. From these it will be seen that the gross receipts (including the balance brought from last account) amount to £23.611. 4s. 4d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable, and the expenses in connection with cable repairs) to £11.209. 12s. 4d., leaving a sum of £12.401. 12s. to the credit of revenue account. Of this the sum of £2.500 has been added to the reserve fund, increasing that fund to £93.500. The dividend on the Preference shares will absorb £3.000, and leave £6.901. 12s., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, the balance, £501. 12s., being carried forward to the current half-year's account.

The unusually large sum borne by the revenue of the half-year for repair of cables has been expended upon the Batabano-Cienfuegos Cable, which has been repaired three times, having twice been damaged by ships' traffic, and upon the Cienfuegos-Santiago 1875 Cable, which has been thoroughly repaired. Both these cables are now in good working order.

A contract has been entered into with Messrs. Hooper, of Hooper's Telegraph Works, for the laying of a new cable between Batabano and Cienfuegos, which will be completed in a few months: when this is finished the whole of the Company's cable system will be in duplicate.

No progress appears to have been made by the French Cable Company in its scheme to lay cables along the north coast of Cuba in competition with this Company's cables along the south coast of the island, the Spanish Government having postponed further consideration of the terms of the proposed concession to the French Company until judgment has been given in this Company's action for the protection of its rights—rights which would necessarily be seriously prejudiced by the new scheme if a concession were granted.

The Director who retires from the Board at this time is Mr. Alexander F. Low, who, being eligible, offers himself for re-election. Mr. John Gane, the auditor, also retires, and offers himself for re-election.

Chili Telephone Company (Limited).

Report of the Directors to the shareholders, to be presented to the first ordinary general meeting, to be held at Winchester House, Great Winchester-street, E.C., on Friday, August 8, 1890, at noon.

The whole of the 40,000 shares offered in August last were subscribed for and allotted, and the full sum of £5 has been since received on each share.

Digitized by Google

The purchase money of the properties in Santiago, Valparaiso, Concepcion, Iquique, Chillan, Talcahuano, Talca, Pisagua, Serena, Coquimbo, Tomé, Penco, Coronel and Lota, has not yet been paid in full to the vendors. The transfer of these properties was, in due course, made to this Company by the vendor Company in America; but some shareholders of that Company resident in Chili obtained an injunction to restrain the legal registration of the transfer, with the view apparently to secure to themselves a larger proportion of the vendor Company's assets than would fall to them upon a *pro ratâ* division with the shareholders in America. The action in the Chilian Court is between the vendor Company and a small minority of its shareholders. This Company is not a party to it, but the Board has used, and is using, its best endeavours to remove the impediment to the legalisation of the transfer. Negotiations are reported to be pending to settle the differences by compromise or arbitration; either mode would raise the injunction, and allow registration to be completed.

After much correspondence and considerable loss of time, the vendor Company appointed this Company's General Manager in Chili to be the General Manager of the vendor Company there, and consequently, since that appointment the business has been conducted without serious inconvenience.

The business has been carried on for this Company since May 1, 1889, and the net profit to March 31, 1890 (after providing for the extraordinary depreciation in currency) amounts to £5,520. 8s. 1d. The Directors recommend a dividend of 2s. 6d. per share, being a fraction more than at the rate of 5 per cent. per annum from the time the capital has been received to the 31st March last; this will leave £520. 8s. 1d. to be carried forward to the account of the next year.

The business is progressing satisfactorily.

—	May 1, 1889.	March 31, 1890.	Increase.
The number of subscribers was.....	2,070	2,868	798
The gross revenue was at the rate per annum of	$225,357	$300,346	$74,989
The mileage was	2,523	3,320¾	797¾

The above increases were during eleven months only. The General Manager in Chili has every confidence that, in the current year, very much more favourable results will be shown, and his estimate of improvement is confirmed by a continuous and rapidly-increasing demand for telephones.

Negotiations have lately been opened for the sale to this Company of the property, plant, and business of the National Telephone Company of Chili (National Company Telephonos Chile), in Santiago and Valparaiso, and the Directors have been advised by cablegram of the purchase of the whole for £36,000. That Company was the only competitor with this Company, and the Directors having now, practically, the control of the telephone business in Chili, anticipate that the Company's revenue will be considerably increased; while the requirements of the public will be fully met, by necessary extensions, and moderate and more uniform charges.

In accordance with the Articles of Association, the Hon. F. Ernest Allsopp and Mr. Thomas Greenwood retire from the Board of Directors, but, being eligible, offer themselves for re-election. The Auditor, Mr. Thomas A. Welton, also retires, and offers himself for re-election.

NEW COMPANIES REGISTERED.

EARTHY METALS COMPANY (LIMITED).—Registered with a capital of £2,000 in £50 shares. Objects: To carry out an unregistered agreement with Luis Falero. To produce and prepare for market, sodium, potassium, magnesium, aluminium, and other metals, and to carry on business as metallurgists, manufacturing chemists, and of makers of and dealers in electrical, chemical, and scientific apparatus and materials.

FRANCO-AFRICAN LIGHTING SYNDICATE (LIMITED). — Registered with a capital of £25,000 in £1 shares. Objects: To carry on in Algeria, Tunis, or other part of the French dominions or protectorates, the business of a gas or electric light company in all branches.

PLYMOUTH AND DISTRICT PULSION TELEPHONE COMPANY (LIMITED).—Registered by Sir Joseph Causton and Sons, 9, Eastcheap, E.C., with a capital of £4,600 in £1 shares. Object: To carry on the business of a telephone company, and for such purpose to purchase the patent rights granted to Lemuel Millett for improvements in a mechanical telephone known as the Pulsion telephone.

WOODWARD, GROSVENOR AND COMPANY (LIMITED).—Registered with a capital of £90,000 in £10 shares. Objects: To take over the businesses of Woodward, Grosvenor and Co., and the Stour Vale Mill Company, carried on at Kidderminster and 102, Newgate-street, and to trade as carpet manufacturers, spinners, general merchants, engineers, electricians soap and glue manufacturers, &c.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 25th amounted to £4,750.

BRIGHT PLATINUM PLATING COMPANY (LIMITED).—On the petition of G. Twynam, a judgment creditor, Mr. Justice Stirling, on Saturday, ordered this Company to be wound up.

CHEMICAL CARBON COMPANY (LIMITED).—It has been resolved to wind up this Company; and Messrs. Dowling and Purberry, of Basingstoke, have been appointed liquidators.

EDWIN FOX AND COMPANY (LIMITED), IN LIQUIDATION.—A meeting was called for Wednesday last by the "Committee of Inspection," to take counsel with the creditors of the Company as to the advisability of taking action against the late Directors of the Company. In the circular issued, many grave charges are brought against the late management.

INTERNATIONAL CABLE COMPANY (LIMITED).—The petition of Alfred Sohier Bolton, member of a large firm of wire manufacturers at Cheadle, for the winding up of the International Cable Company (Limited), was again before Mr. Justice Stirling on Saturday; and, after hearing Mr. Buckley, Q.C., on behalf of the Company, his lordship, without calling on Mr. Graham Hastings, Q.C., to reply, made a winding-up order in the usual form.

MUTUAL TELEPHONE COMPANY (LIMITED).—At a meeting of the shareholders of this Company, recently held at Manchester, Mr. A. D. Provand, M.P., in the chair, resolutions were passed increasing the capital from £100,000 to £350,000, in order to allow an extension of the Company's field of operation, and altering the Articles of Association so as to permit interest to be paid up to 10 per cent., instead of 6 per cent.

STOCK EXCHANGE.—Application has been made to the Committee to allow Elmore's Patent Copper Depositing Company (Limited) vendors' shares, to be quoted in the official list.

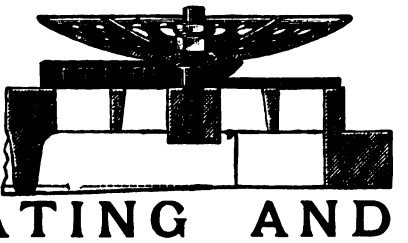
WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—At their meeting on Wednesday the Directors declared an interim dividend of 3s. per share, tax free, in respect of 1890.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 25, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,679.

WESTINGHOUSE ELECTRIC COMPANY.—At a meeting of the stockholders of this Company, recently held at Pittsburg, Pa., it was announced that an increase in the capital stock of not less than $5,000,000 was authorised, each stockholder being entitled to subscribe for one-half share of stock for each share now held by him at $40 per share; and it was stated that Mr. George Westinghouse, jun., had agreed to take a fourth of the new issue on those terms. The central station ordered by the Metropolitan Electric Supply Company (Limited) in London was in operation, and was the most complete and perfect central station in Europe. The English Company formed to work the Westinghouse patents was a great success, and the business abroad bids fair to be a source of great profit to the parent company.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 638.—Vol. XXV. FRIDAY, AUGUST 8, 1890. Price Fourpence.

NOTES.

He who would venture to define the whole duty of a consulting engineer may reckon on the loss of some friends; and any learned Institute that might essay the task would infallibly make many enemies. The London Chamber of Commerce might discuss it, but their resolutions would bind no one. The Institution of Electrical Engineers would probably shirk it; although the Royal Institute of British Architects have not only successfully framed careful rules, but prescribe fees. We have no intention of grappling with the problem; but we are bound to notice special cases when complaints reach us, for such complaints need ventilation. One question was alluded to in the correspondence columns of our last issue, and an evil arising from this same question was discussed briefly by one of our contemporaries last week. It is, however, a matter concerning the true consulting engineer with which we have to deal at present, and not the contractor who dabbles in a practice which should be distinct from his own.

The Corporation of Brighton, for it is useless to disguise the names and particulars, allowed a somewhat discreditable muddle to take place some months ago; and, when that was all over, Mr. Shoolbred was instructed to prepare a specification and plans for the electric lighting. This, of course, they were justified and well advised in doing. But, before they had made sure of getting the money necessary for carrying out the work, they instructed their consulting engineer to invite tenders. This he did, on the authority of the Corporation. We have seen neither the Bradford specification nor that for Brighton, and are not prepared to criticise them from hearsay. A specification for the lighting of a town unfortunately follows no precedent or established form. It may give no more than a schedule of the lights, an indication of the site, or a choice of sites for the station, and a few general conditions. If the consulting engineer is asked to give no more than this, throwing the whole of the design upon the contractors, it does not follow that the results will be unsatisfactory, for he may carefully select the best scheme, and conscientiously see that it is carried out. Such a course entails an expense of, say, fifty pounds on each contractor, in calculations, visits, drawings, and estimates. The terms may be more precise, varying from a mere schedule, up to the specification which was drawn up for St. Pancras. Experience has shown that the full detail, including quantities, which the architect provides, is the most satisfactory to all parties; and Local Authorities should stipulate and pay for a complete specification, about which there can be no uncertainty.

We were surprised to find an unusually large difference between the highest and the lowest tenders in the list which we published on July 25th; and further to find that several firms sent in two tenders for dynamos, and Messrs. Siemens and Co. no less than four. We understand that the specification was very precise in some details, such as the manner of mixing the concrete; and, on the other hand, no proper drawings were provided, and not even a maximum speed for the engines or dynamos was specified. Even if the pressure or the system had not been defined, the matter might have been settled satisfactorily by a careful selection of the best. But we are informed that after the Corporation (having at the time no funds for carrying out the work) had received the tenders, they "allowed them to be messed about," how, or by whom, we know not; but with the result that certain contractors were asked to tender again, and others, some of them leading firms, were not invited. We have not inquired whether the specification for the second batch was identical with the first, or whether it had been amended, or whether the amendments, if any, had been suggested by some of the first tenders. At all events, the proceeding was one which is unworthy of a body in the position of the Corporation of Brighton, and which, as it has caused considerable irritation, we hope will not be repeated. We understand that the specifications for the St. Pancras lighting were very complete, and gave a full bill of quantities; but the result, as given in the list of tenders which will be found at the end of this issue, does not show any closer running as to prices. Messrs. Siemens and Co. is not the only firm who have in this case also had more than one bite at the cherry.

If rumour speaks truly, a very important advance has just been made in electro-metallurgy. Hitherto it has been found impossible to produce by electro-deposition a satisfactory plating of aluminium. The word "impossible" possesses, however, no finality to the electrician; and we hear with great satisfaction that one of the most enterprising of electrical firm has just made arrangements to secure and develop the newly-invented process for the deposition of aluminium, and of some new alloys which, apparently, have uses of very great importance.

Digitized by Google

THE Southwark Subway, the progress of which has been watched with interest, is not easily recognisable under its new name of the City and South London Railway. The report, which we publish in another column, gives no ground for the supposition that there has been any hitch in the work. That electric railways and tramways have sometimes been opened before the work was half finished is no reason why any undue haste should be made in this case, in which stations have been built and fitted. Mr. GREATHEAD'S line is far more likely to be a success than if a few sneers at the apparently slow progress had induced him to hurry the construction and to make a premature start.

THE concluding Paper of the Institution of Electrical Engineers at Edinburgh by Mr. A. R. BENNETT described a number of experiments with radiometers. The majority of these were due to thermal effects and to air currents, and the direction of rotation seems to have been very uncertain and capricious. Two or three experiments employed electricity. In one of these the vanes were fitted with metal caps working on wire pivots fused in the glass. Such radiometers, Mr. BENNETT says, form condensers having the inner coating, the vane, free to move. The dielectric is the rarefied air, and the glass the outer coating. When the vane is connected to one pole of an influence machine, it rotates until the condenser is charged, and then stops; when the current is arrested, the vane rotates again in the same direction, until the greater part of the charge is lost. The action is increased by coating the outside of the glass with tinfoil. Mr. BENNETT'S experiments appear to be due to the combined effect of an ordinary brush discharge, and of the more refined actions which have been investigated by Mr. CROOKES in high vacua.

FEW if any of us pay rates and taxes with perfect spontaneity; and, therefore, the Institution of Civil Engineers is, we suppose, to be congratulated on having succeeded in resisting the demands of the Commissioners of Inland Revenue, who claimed 5 per cent. of a certain portion of their income. The decisions of the judges contain examinations into the meaning of the word "science," and more than one encomium on the value of the "body politic" to whose hospitality electrical engineers are so much indebted. "Any man who wants most effectively and successfully to practise the profession of a civil engineer will join the Institution," "I cannot conceive in what better way the promotion of mechanical science, and in particular of those branches of mechanical science which lie within the province of civil engineering, could be effected."

THE article by Mr. BATHURST in the *Electrical World*, of which we give an abstract in another column, though it is of a lower order of merit, may be taken as the complement to the Paper read by Mr. ADDENBROOKE last winter on "Electrical Engineering in America." The apology for ugly and cheap work is clearly made. The author does not appear to suggest that the "open cleat work" is more likely to give rise to accidents than the more neat-looking English style. It is rather amusing to learn that the author has been unable to obtain any actual figures of insulation resistances of the popular method of wiring.

ONE interesting point in this account is the comparison between "centre distribution" and the "free system." We do not remember having heard these terms before; but the latter evidently means the method of wiring with mains, sub-mains, branches, and smaller branches, which we hope is not so common as Mr. BATHURST seems to imagine. The "centre distribution" means the method of tapping from the mains as many branches as there are lights, or at all events one for each switch. It appears to us that the questions of the cost of labour and the cost of copper are quite insignificant here, as compared with the great advantage of grouping all the joints and therefore all the cut-outs in one accessible spot. An old excuse for bad joints used to be that they were placed in an awkward position, and there was no room to handle the soldering iron; and the excuse was as reasonable as the directions of the engineer who suggested the position of the joint were unreasonable. The cut-outs should be placed in an easily reached and convenient position, and such a position will allow the jointer to do good work. Soldered joints under the floor are an abomination; they are difficult to make, and impossible to inspect. In our opinion, the whole of the lights on each floor of an ordinary house should be run on separate circuits to the mains, and these should run nearly to the top of the house.

THE first, and probably the last, execution by electricity has taken place in America. We presume that all who were concerned in the matter are so ashamed of themselves that comments are superfluous. For sensational accounts of disgusting details we refer our readers to other journals.

THE sum of £47,500 payable as to £23,000 in cash and £24,500 in the fully paid-up shares of a company with a capital of £100,000, is an altogether absurd price to pay for machines to drill square holes. We saw a machine drilling square holes at the Exhibition at Paris in 1878, and believe that another was shown at the Inventions Exhibition. We did not pay attention to the present tools until they had been noticed at some length by our contemporaries. On the occasion of our visit the machines could not be said to be drilling;—they were merely scraping away the metal. No such thing as a clean cut-out boring was to be seen. The tool scrapes with one edge, and is subject to severe side strain. The statement in the prospectus that "a driller will be able to turn out work as accurately as an experienced fitter has hitherto been able to do" is greatly exaggerated, and we saw no grounds whatever to support the statement that "the relative cost of drilling round holes and making square holes was in the proportion of about 1 to 36," and that "a square hole can now be drilled by the company's drilling machines at about the same cost as a round hole." We do not know who wants to drill square holes; in the list of trades who are expected to do so, watch and clock makers and turnkey makers are given: surely it is not expected to make watch-keys thus?

Digitized by Google

One of the only uses we can think of is the making of box-keys. Reports and opinions as to the validity of the patents are alluded to, but no engineer's or manufacturer's opinion as to the practical value of the invention is given.

We have been expecting it for a long time past, and it has come at last. The phonograph, after attempting to pose as a scientific instrument, then as an indispensable adjunct to every well-appointed office, and, failing that, as a means of entertainment at parties and *conversaziones*, has at length found a resting place in the squeaking doll. It was obvious so soon as she was taught to say "mamma" and "papa" that her education would have to be completed, and this by means of the phonograph. As a nursery plaything, or in any other equally humble capacity, Mr. Edison's much-belauded patent will do some service. For one thing it may be trusted not to talk as much nonsense of itself as is talked about it; and our children as they grow up will discover, what their parents appear to be unable to realise, that the phonograph is not an electrical appliance. If we are not mistaken, it was announced a long time ago that a very large consignment of improved phonographs had left New York in a specially chartered vessel. We fear she must have gone down with all hands.

Marthalen.—The village of Marthalen, in Zurich, has adopted the electric light in its streets.

Kidderminster.—The Corporation have resolved to apply for a Provisional Order for electric lighting.

Bellinzona, Switzerland.—The Town Council has decided to carry on electric lighting. The work is to be entrusted to Messrs. Alioth, of Basle. It is to be completed by November 15th, at a cost of £5,200.

Electric Lighting in Edinburgh.—It was agreed on July 31st to recommend the Edinburgh Town Council to take steps to obtain a Provisional Order giving them power to control the introduction of electric lighting into the city.

The Gas of Cork.—In the course of a judgment at the recent Cork Assizes, on a dispute about some gas burners Mr. Justice Gibson said, "Cork gas appears to be a peculiar article, odoriferous, and giving a sickly and insufficient light."

Verona.—The installation at Verona, which was entrusted to Messrs. Schuckert and Co., Nuremburg, is nearly completed, and it is expected that 30 arcs and 1,200 incandescents will be at work this month. Low-tension continuous currents are used.

National and Colonial Exhibition in Lyons.—A National and Colonial Exhibition will take place in Lyons during the year 1892. The sections for silk and electricity will be international, and a special section, without competition, will be reserved for the foreign exhibitors.

Bromley.—The local syndicate for electric lighting at Bromley have resolved that they will not favour any particular company in carrying out their scheme, but will employ their own engineer to get out estimates, and then invite tenders from some of the best firms.

Southampton.—At a meeting of the Town Council on Wednesday it was decided, by 18 votes to 6, to decline to purchase the licence of the local electric lighting company for £750. It was argued that the Corporation should do the lighting, and that in no other instance had any such rights been purchased.

Cassel.—The local authorities have decided on the erection of a central station, and have accordingly purchased some mills on the river 2½ miles above the town for £13,250. At present 3,000 incandescent lamps are to be installed, but this number is to be largely increased; 2,800 private incandescent lights have also been applied for, besides a number of arcs.

St. Helen's.—The Corporation have received notice from the Electric Installation and Maintenance Company (Limited) and the Lancashire and Cheshire House-to-House Electricity Company (Limited) of their intention respectively to make application to the Board of Trade for a provisional order. The Gas Committee recommend the Corporation to oppose the applications.

Telephone between Paris and Bordeaux.—The City of Bordeaux some time ago asked for a telephonic line to Paris. M. de Selves, of the Administration of Telegraphs, has informed the Mayor that the erection of the line will be commenced as soon as the Municipal Council of Bordeaux votes £18,000 (450,000fr.) as representing their share of the expenses demanded by the State.

Underground Mains in Paris.—Contractors have been obliged to place their mains under the pavements at a distance of at least one metre from the façades of the houses, thus keeping a space for municipal mains. M. Cochin remarked at a recent meeting of the Municipal Council that in certain streets the pavements are less than one metre wide. It was decided that where necessary the limit should be reduced to 60 centimetres.

The Copper Ring.—The Court of Appeal in France has decided that the coalition between M. Secrétan and the Copper Mining Companies was not illegal, since each company was perfectly aware that there were contracts with other mines. Moreover, in no contract had M. Secrétan engaged those who combined, not to sell or to sell only at a fixed price. The sentence of six months' imprisonment is not, however, modified, although the fine of 10,000fr. is reduced to 3,000fr.

Electric Light at the Vienna Stadthaus.—This installation is to be increased to 3,536 glow lamps, the present number being 2,756, so that it already ranks as a large private installation. From the *Zeitschrift für Electrotechnik* we learn that the laying of the conductors of the International Elektricitäts Gesellschaft in Vienna is being rapidly proceeded with. The primary conductors are now laid throughout the whole circuit, and the secondary conductors are now being put down.

Telephone in the West Riding of Yorkshire.—It is intended to charge five guineas per annum for every instrument, and in cases where more instruments than one are employed on the same premises, one guinea each, and it is proposed to establish inter-town communication with an exchange. To begin with, the promoters wish to extend operations to five large towns in the West Riding, namely, Leeds, Bradford, Halifax, Dewsbury district, and Huddersfield. It is proposed to have a double circuit of wires.

Breslau.—The Town Council has decided to grant 1 million marks (£50,000) for the erection of a central station. The project of Messrs. Siemens and Halske will probably be accepted. The central station will at first have a capacity of 8,000 lamps, to be afterwards increased to 30,000. Continuous currents will be used, and the lamps within a radius of 1,200 metres will be fed directly from the machines. Outside the limit, the system will be supplied by accumulators charged during the day.

Cologne.—The municipal installation is being pushed on with. Owing to the ground under the streets being already crowded with gas and water mains, the lighting cables will be laid principally under the pavements. At first, the main thoroughfares only of the old part of the town are to be lighted, for which 12,000 lamps are required. For the supply of these, two steam engines of 250 horse-power and two of 500 are to be put down. The price to be paid is 6·06 pf. ($\frac{3}{5}$d.) per 16 candle-power lamp hour, which appears rather high.

New Insulating Materials.—A series of new insulating materials have been discovered by Mr. G. E. Heyl, of Charlottenburg. To one of them he has given the name, Heylit; it is made in three grades, melting at 60deg., 100deg., 120deg., and 180° C. respectively. A sheet of the last grade, 10cm. square, and 1mm. thick, has a resistance of $19{,}300 \times 10^6$ ohms, as shown by tests made at Munich laboratory. It is claimed that the new insulating material gives a lower capacity and higher insulation than any of the ordinary insulators. It is also much cheaper, and is unaffected by acids or chlorine.

Digitized by Google

Dusseldorf.—The *Koelnische Zeitung* reports that on the 29th July the Corporation of Düsseldorf-on-the-Rhine have resolved to erect a central electric lighting station for about 20,000 incandescent lamps at the amount of two millions of marks, with direct current and accumulators. The main station is to be built near the new gasworks, two smaller stations in the Bleichstrasse and the Grünstrasse. After a Paper read by the consulting electrician, Prof. Kittler, of Darmstadt, the execution of the total plant was laid in the hands of Messrs. Schuckert and Co., Nuremberg.

Electric Lighting at Exeter.—The Special Committee appointed to consider whether the Council should themselves apply for a Provisional Order for the supply of electricity for public and private purposes within the city of Exeter, recommended that the Exeter Electric Light Supply Company be requested to supply a draft of their proposed Provisional Order within six weeks, and that a special meeting of the Committee be called to consider the same, and that in the event of no draft being submitted by that date, a meeting of the Committee be convened to consider the course the Council should adopt. After a little discussion the report was adopted.

Search Lights for Military Purposes.—Not long ago, says the *Army and Navy Gazette*, interesting manœuvres were gone through at Tempelhof with the object of testing the value of the electric light for discovering the advance of an enemy seeking to surprise a position by night. The necessary arrangements were made by the pioneers of the Garde, who erected dynamos and established lamps with powerful reflectors. In the evening the 2nd Battalion of the 3rd Regiment of the Garde arrived on the spot to dig trenches, and some companies of pioneers, screened by the railway embankment, were to attack them in their work. Briefly, the attack failed, for every movement of the advancing party was clearly distinguishable from a great distance.

The French Submarine Cables.—In reply to Mr. Henniker Heaton, Mr. Raikes said last week that a substantial profit will no doubt result from the purchase of the submarine cables between this country and the Continent, but it would be premature at present to estimate the amount of that profit in view of the condition of the cables. Some of these cables are very old, and it is possible that before long a considerable expenditure may have to be incurred in renewals. The number of words in Anglo-French telegrams has risen from 13,376,333 in the year to March 31, 1889, to 15,495,791 in the year to March 31st last. Other telegrams have passed over the Anglo-French cables, but he was not able to give separate particulars with regard to them.

St. Moritzbad.—According to the *Elektrotechnische Zeitschrift* the alternating-current scheme for this central station is to be abandoned. The turbines, &c., are to be to the plans of Messrs. Largin and Grossman, Lucerne. Three Girard horizontal turbines, supplied by Rieter and Co., developing 160 horse-power at 250 revolutions, will be put down. The power will be sufficient to run 4,000 lamps, but it is considered advisable to be able to augment this, so that probably accumulators will be used. Four continuous-current machines will be driven in series, and will supply a current at 8,000 volts to the transforming station, which is six miles distant. Here eight transformers will reduce the tension to 100 volts, the three-wire system being used. It is stated that this change is due to the advice of Herr Uppenborn.

The Victoria Torpedo.—Messrs. Heenan and Froude are manufacturing a torpedo, invented by Mr. Murphy, of Melbourne. It will, according to *The Times*, have a range of 2½ miles; it is 24ft. in length, and is driven by a screw-propeller, worked by compressed air. The steering and control are effected by electricity, by means of three lines of seven strands each, forming a cable which weighs 1½oz. to the yard. The torpedo carries 1,200 yards of cable coiled up in a free coil in a chamber full of oil. When the torpedo is started, cable is payed out from shore; but after a certain speed is attained, for every yard payed out from shore nine yards are uncoiled from the torpedo. Three motors, weighing 2lb. 7oz. each, are carried; and these control the rudders, starting gear and the exploding arrangement, each electrical impulse giving a definite effect.

Injuries and Death from Lightning.—On Saturday afternoon during a cricket match at Aldershot a brilliant flash of lightning, followed by a loud peal of thunder, appeared to strike a tree under which some soldiers were seeking shelter. Surgeon Frank, of the Medical Staff, rushed to the spot with the rest of the players, and after untiring efforts at resuscitation successfully restored five of the six men who had been struck. One, however, was found to be lifeless. The tree around which the group of men were sitting showed no mark except at the base, where the bark for about two feet was stripped away. It was stated at the inquest that had it not been for Surgeon Frank, the other men would have died; but, as the result of his persistent efforts to restore animation by means of artificial respiration, especially in the case of Private Evans, who was supposed to be dead, they were all saved.

Electric Tramway on Southend Pier.—The electric tramcar on the Pier at Southend has been completed by Messrs. Crompton and Co. The engine, boiler, and dynamo are situated under the arches close to the entrance of the Pier, and the current is conducted along the central rail for three-quarters of a mile down the Pier. The car holds about 40 persons, and travels at the rate of about 16 miles an hour, making a journey in about 3½ minutes which takes nearly 15 minutes by the ordinary horse traction. The line was certified by Dr. Hopkinson on Friday last. On Saturday afternoon, after a few trial runs, it was handed over to the Local Board for public use at four o'clock. A large number of people availed themselves of it; and on Monday, Bank Holiday, the car was well patronised. This is a very satisfactory exhibition of electric traction; and as it is situated only a short distance from London, it will, no doubt, be visited by many interested in this particular work.

The Institute of Medical Electricity.—This Institute has recently removed to larger and more commodious premises at 35, Fitzroy-square, W. Increasing work, and the need for being nearer the great medical centres of Harley-street and Wimpole-street, induced the Directors to make the change. They have taken one of the old-fashioned substantial residences on the Grafton-street side of the square, and it contains many large, light and airy rooms well adapted to the purposes of the Institute. The drainage has been entirely renewed, and the house redecorated from attic to basement. The apparatus has been carefully removed from the old quarters at 24A, Regent-street, and new has been added to it, so that greater facilities are now available for electrical treatment, which is carried out only under medical sanction. Increasing use is being made of treatment by "cataphoric medication," or the passage of drug solutions through the skin by means of electric currents. This method of obtaining strongly localised action has been developed from its experimental stage, and first brought into practical use at this Institute under the auspices of Dr. Arthur Harries and Mr. H. Newman Lawrence.

Manufacture of Vermillion by Electrolysis.—In a wooden vat, one metre in diameter and two metres deep, circular plates 15 centimetres wide are placed against the sides, and on these the mercury is exposed, one centimetre deep. These plates are connected with the positive pole of a dynamo. At the bottom of the vat is a sheet of copper electroplated with iron, and connected with the negative pole. The vat is filled with a solution of 8 per cent. of nitrate of ammonia, and 8 per cent. of nitrate of soda. A worm, pierced with holes, supplies a constant and regulated current of sulphuric acid; the excess of gas escapes by a tube projecting from the lid. A screw agitator keeps up a thorough mixture in all parts of the liquid. When the current passes it immediately forms a precipitate of red sulphide of mercury. Attempts have been made to dispense with the current of sulphuric acid by making up the bath with:—Water, 100 litres; nitrate of ammonia, 8 kilos; nitrate of soda, 8 kilos; sulphide of soda, 8 kilos; sulphur, 8 kilos. Under these conditions one need only add sulphur and mercury to extract at the end of the operation vermillion which rivals that which can be obtained by sulphate of ammonia.

Heilbronn.—We learn from the *Elektrotechnischer Anzeiger* that the terms of the contract for the supply of light and power in this town were definitely settled upon at the last

Digitized by Google

meeting of the Town Council. By this agreement the cement factory at Lauffen-on-the-Neckar, which has about 1,200 superfluous horse-power at its disposal, obtains the sole right to supply the town with electricity for a long term of years. The tariff is fixed on the basis of a charge of 3pf. (0·36d.) per lamp hour for 10 candle power lights, with a yearly demand of 300 hours, and 2·4pf. (0·29d.) per hour if the yearly demand reaches 1,000 hours. For power, 27pf. (3¼d.) per horse-power hour are to be charged for a yearly consumption of 1,000 horse-power hours, with a reduction to 15pf. (1¾d.) per hour if 3,600 horse-power hours are taken in the year. These prices are considerably below the cost of power obtained from any other source. As already more than half the available power has been subscribed for, accumulators will probably have to be used. The installation is to be proceeded with at once, so that it may be got to work before the close of the present year. The capital of the Company is to be increased by 300,000 marks (£15,000).

The Utilisation of Waste Coal.—The Commission recently appointed by the Legislature of Pennsylvania to consider the question of coal waste, and to devise, if possible, some means of utilising the culm, has commenced its sittings. The Commission consists of Colonel J. A. Price, President of the Scranton Board of Trade; Mr. P. W. Sheafer, a distinguished mining engineer, of Pottsville, and Mr. Eckley B. Coxe, a well-known coal operator. Mr. Sheafer has estimated that there are 100,000,000 tons of waste coal in the anthracite regions. A portion has been destroyed by fires, which often burn for years in a culm bank; and much of it is mixed with slate, ashes and stones, so that it is worthless. The most valuable banks of waste are those where the small coal has been kept separate from slate and ashes. The utilisation of this immense quantity of waste is a very important matter, and the Commission will aim to find out if that which is now a source of expense cannot be made a source of revenue. It is interesting to note in this connection that at Scranton the culm coal from the pile adjacent to the generating station of the electric tramway is used, the price paid per ton being 5d., which results in the cost of coal per car mile coming out at ·014d. per car mile, as against ·25d. at Cleveland and ·36d. at Washington.

Extension of Electric Lighting at the Central Station, Glasgow.—Contracts have been closed for an extension of electric lighting at the Central Station of the Caledonian Railway, the contractors being Messrs. Mavor and Coulson, George-square, Glasgow; and within the extension there will be included the whole of the hotel premises, all the station offices, the booking offices, platform bookstalls, stores, &c. The present engine-room, which is on the basement floor, underneath the passenger station, is to be entirely remodelled; and the engine, which at present generates the current for the arc lamps over the passenger platforms and elsewhere, and for the incandescent lamps in a portion of the hotel, will be removed, and two new engines will in due course be installed for the permanent lighting. There will be two powerful dynamos, each being capable of supplying current to about 650 16 candle-power lamps, and one having about half that capacity. The speed of these machines will be 600 revolutions per minute. In all there will be from 1,600 to 1,700 lamps in the installation when it is completed. Provision has to be made in the wiring for circuits to replace those already in use. The wiring in the hotel is to be done in sections, two on each floor, and it is to be done under teak or other hard wood, so as to match, as far as possible, the woodwork of the various rooms. Some of the light being required during the day, one of the engines will always be running. The work has already been commenced by Messrs. Mavor and Coulson, and the intention is have to it finished in the course of three months—that is to say, by the end of the month of October.

Diamagnetism Tested by Carnot's Principle.—In a recent number of the *Philosophical Magazine* appeared a short Paper by Mr. J. Parker, of Cambridge, in which Carnot's principle was applied to diamagnetism. An oversight occurs in the Paper, which has since been corrected by M. Duhem, who has adopted and extended the substance of the Paper. The present state of experiment and theory on diamagnetism may be briefly stated thus:—(1) If a piece of bismuth be placed near a strong iron magnet in the open air, the bismuth behaves as if repelled by the iron. (2) If the same experiment were performed in a vacuum, it is shown by Carnot's principle that the bismuth would not be repelled, and might be attracted. It is therefore concluded that if the experiment were performed in a place from which the air could be pumped away at will, the repulsive force on the bismuth would become zero when the pressure of the air was sufficiently reduced, and by continuing the exhaustion still further it would probably become attractive. The action of the bismuth in the open air will be explained if one remembers that both the iron and the bismuth are surrounded by a mass of magnetised air, so that the behaviour of the bismuth is due to three causes—(1) The attraction of the iron magnet. (2) The attractions of the magnetised atoms of air. (3) The resultant of the unequal pressure of the air over the surface of the bismuth. The conclusions of this Paper naturally lead us to question the propriety of making our "absolute" units of electricity and magnetism depend on the actions between bodies surrounded by electrified or magnetised air, about which all that is known is that, at some distance away, the air with which it is in equilibrium has a measurable pressure.

The Electric Lighting Acts.—The report by the Board of Trade respecting the applications to and proceedings of the Board under the Electric Lighting Acts for the past year has just been issued. It is a very elaborate document, and contains a complete list of all the Orders and applications for Orders, with statements of reasons for refusal in cases where the application was not granted. We take the following epitome from *The Times*:—There were 161 applications, of which 45 were made by local authorities and 116 by companies or individuals; 23 related wholly or in part to the county of London. A large number of the applications related to districts outside the metropolitan area; and it was found that considerable alterations would be necessary before the model form of Order settled last year for the metropolis could be made applicable. The Board of Trade therefore settled a model form of Provisional Orders based upon those confirmed by Parliament last Session which would be applicable to—(1) Orders granted to Local Authorities, and (2) Orders granted to companies outside the Metropolis; and which, in the case of the Metropolis, followed as closely as possible the forms adopted last year. The Orders granted to companies have, in every case, been granted with the consent of the Local Authority of the district; but, in one instance, the Board of Trade considered it necessary to hold a local inquiry. In several instances, applications were received from the Local Authority and also from one or more companies from the same area. In such cases the Board of Trade have, in accordance with their rules, given the preference to the application of the Local Authorities. In the Orders and licenses granted to Local Authorities the Board of Trade have, after careful consideration of the representations made to them in favour of such a course by the Local Authorities acting as representatives of the ratepayers, inserted a clause authorising the Local Authority to transfer their powers, duties, and liabilities to any company or person with the consent of the Board of Trade. The regulations prepared by the Board of Trade for the purposes of Section 4 of the Electric Lighting Act, 1888, referred to in the last report, have been settled, and in any case in which their attention has been called to the existence of overhead electric lines to which that section would apply, a notice has been served by the Board of Trade upon the owners or users of such lines requiring them to comply with the regulations. These regulations are given in an appendix to the report. A question having arisen as to the interpretation to be placed upon the portion of the schedule of the Electric Lighting Act, 1882, defining Local Authorities in Scotland, the Board of Trade consulted the Scotch Office, who were of opinion that in certain cases in which authorities in Scotland were authorised to supply gas, they were not the Local Authority for electric lighting purposes in the capacity in which they supplied gas, and would not be able to utilise the gas rates for electric lighting purposes in the event of their obtaining powers to supply electrical energy. A Bill to amend the schedule was therefore introduced.

MAGNETISM IN IRON AND OTHER METALS.*—XXVI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 340.*)

§ 98. **Further Experiments with Wrought Iron.**—In the following experiments bobbins were used of a shape suited to give a fair approximation to a uniform field, and hence the outside field close to the neck is taken as the measure of H :—

TABLE XI.—*Lowmoor Wrought Iron.*

H	B	I	μ
3,080	24,130	1,680	7·83
6,450	28,300	1,740	4·39
10,450	32,250	1,730	3·09
13,600	35,200	1,720	2·59
16,390	36,810	1,630	2·25
18,760	39,900	1,680	2·13
18,980	40,730	1,730	2·15

TABLE XII.—*Swedish Iron,* "L[S]Lancash." *Brand.*

H	B	I	μ

3,600	24,650	1,680	6·85
6,070	27,130	1,680	4·47
8,600	30,270	1,720	3·52
18,310	38,960	1,640	2·13
19,450	40,820	1,700	2·10
19,880	41,140	1,700	2·07

TABLE XIII.—*Fine Swedish Iron,* (L) *Brand.*

H	B	I	μ
5,310	25,670	1,620	4·83
17,680	38,080	1,620	2·15
19,240	39,540	1,620	2·06

In this last iron, which is described as the finest and most expensive iron used in commerce, made by the Walloon process, the saturation value of I seems to be specifically rather less than in other brands. The saturation value usually found in wrought iron may be stated to be, in round numbers, 1,700. The state of saturation is practically reached, in soft metal, with a force of, say, 2,000 C.-G.-S. units; from this force upwards no material change can be observed in I, though the force be increased ten-fold.

§ 99. **Cast Iron and Steel in very Strong Fields.**—In cast iron the highest value to which B was pushed in these experiments was 31,760, with the result of reducing the permeability to 1·9. The saturation value of I in the sample tested was 1,240, and saturation was practically complete under a force of 4,000.

In hard steel the state of complete saturation is not so easily reached. The following test, which was made with a sample of Vickers' tool steel possessing much coercive force, exemplifies this. The test piece formed the central part of a bobbin with wrought-iron cones, built up in the manner shown in Fig. 71. By removing one of the cones, a loose coil on the neck could be slipped off to determine the residual magnetism, which in this case formed a considerable part of the whole. (The residual induction in the neck was about 8,000.) It may be doubted whether saturation was complete even in the strongest field.

TABLE XIV.—*Vickers' Tool Steel.*

H	B	I	μ
6,210	25,480	1530	4·10
9,970	29,650	1570	2·97
12,120	31,620	1550	2·60
14,660	34,550	1580	2·36
15,530	35,820	1610	2·31

* All rights are reserved.

There appear, however, to be specific differences in the saturation values of I in different steels. In the following Table a summary of the results of experiments on other steels is given, showing in each case the highest force applied and the highest induction reached, along with (approximate) corresponding values of I and μ.

TABLE XV.—*Steel of Various Qualities.*

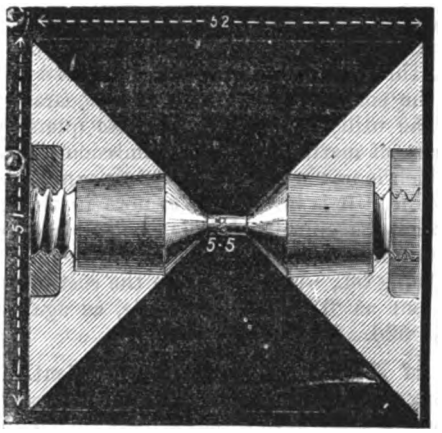

FIG. 71.

§ 100. **Hadfield's Manganese Steel in Strong Fields.**—Reference has been made in § 70 to the remarkable absence of magnetic susceptibility shown by this steel, which contains about 12 per cent. of manganese and 1 per cent. or less of carbon. In fields of ordinary strength this alloy has a sensibly constant permeability of about 1·3, as Hopkinson's experiments have shown.* Application of very strong fields, by means of the isthmus method, shows that the permeability, even under very great forces, remains constant as nearly as may be judged. One might expect that a material which resists magnetisation so strongly would show much coercive force; the reverse, however, is the case. Even the strongest force is unable to produce more than a trace of residual magnetism. The following is one of several experiments which agree in showing that the permeability of manganese steel, under any force up to 10,000 C.-G.-S. units, is practically constant with a value of about 1·4.

TABLE XVI.—*Hadfield's Manganese Steel.*

Digitized by Google

This permeability is so low that when the field is weak, the metal takes up scarcely any magnetism; on the other hand, since the permeability retains the same value in very strong fields, a respectably high intensity of magnetisation may be produced by applying a sufficiently strong force. The variations of μ in Table XVI. are irregular, and are no greater than may be ascribed to errors of observation.

§ 101. **Nickel and Cobalt in Strong Fields.**—With nickel and cobalt a state of complete saturation is reached without difficulty, as the following observations show. In the two specimens of nickel tested (Tables XVII. and XVIII.) the saturation values of I were about 400 and 515 respectively; the difference is perhaps due to differences in the amount of iron present: neither specimen was pure. The saturation value of I in cobalt appears to be 1,300, which is a little greater than the value in cast iron.

TABLE XVII.—*Hard-drawn Nickel (with 0·56 per cent. of Iron).*

§ 102. **Summary of Conclusions from Isthmus Experiments.**—To sum up the results which have been arrived at by means of the isthmus method, the concluding paragraph of the Paper from which these figures are taken may be quoted.*

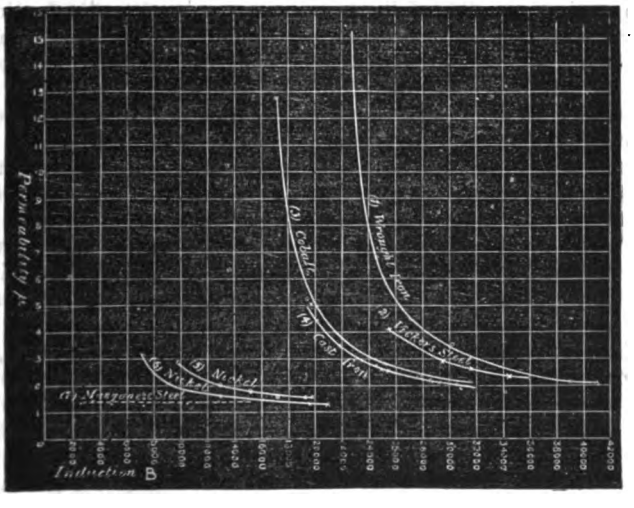

FIG. 72.—Permeability of Magnetic Metals when very strongly magnetised.

Under sufficiently strong magnetising forces the intensity of magnetisation, I, reaches a constant or very nearly constant value in wrought iron, cast iron, most steels, nickel, and cobalt. The magnetic force at which I may be said to become practically constant is less than 2,000 C.-G.-S. units for wrought iron and nickel, and less than 4,000 for cast iron and cobalt. In stronger fields the relation of magnetic induction to magnetic force may be expressed by the formula

$$B = H + \text{constant}.$$

For the particular specimens tested, the value of this constant (4π I) is about 21,360 in wrought iron, 15,580 in cast iron, 5,030 and 6,470 in nickel, and 16,300 in cobalt.

The experiments give a definite meaning to the term "saturation," as applied to magnetic state. When magnetism is measured by the induction B, the term saturation is inapplicable; there is apparently no limit to the value to which the induction may be raised. But, when we measure magnetisation by the intensity of magnetism I, we are confronted with a definite limit—a true saturation value, which is reached or closely approached by the application of a comparatively moderate magnetic force. There is nothing to show that the approach to this limit is not asymptotic; but in wrought iron it is practically reached before the magnetic force rises to 2,000 C.-G.-S., and after that a ten-fold increase in the force produces no material change in the intensity of magnetism.

The results are further summarised in Fig. 72, which gives curves showing the relation of the permeability μ to the induction B drawn from the data supplied by experiments on—

(1.) Swedish wrought-iron (Table XII.).
(2.) Vickers' tool steel (Table XIV.),
(3.) Cobalt (Table XIX.).

(7.) Hadfield's manganese steel (Table XVI.).

(To be continued.)

INFLUENCE OF CURRENT ON THE FRICTION OF SLIDING SURFACES.

Several experiments have been made with the view of determining the effect of current on the friction of sliding surfaces. The results in one case were nil, though the experiments appear to have been carefully carried out; but the current density was small. More than one set of tests has been made with electric tramways, and it has been found that with a heavy current there was a distinct increase of adhesion, and, further, that when this was produced, a distinct pitting of the rails was noticed. It was suggested that a welding action had taken place, and this seems to be confirmed by the experiments of L. M. Schmidt, in the New York *Electrical Engineer*. The apparatus was a modification of a welding machine, the object of the tests being to ascertain whether during the passage of the working current the ordinary sliding contacts of the machine offered any appreciable increase of friction. Three sets of measurements were made—the first, to determine the static friction; the second, the moving friction; and the third, the effect of a lubricant. The static friction cannot be compared with the moving friction, for it appears to us that the effects were simply due to welding. Mr. Schmidt found an increase of the coefficient of friction of repose; a slight decrease of friction of the surfaces while in motion; and a very uncertain and variable effect when a mineral lubricant was used, generally increasing the coefficient of friction. The current density of 150 amperes per square inch of the surface is quite sufficient to account for welding as the cause of the results which were noticed. It is probable that with a good mechanical fit, a higher current density would be required before an appreciable increase of friction would be produced, since the resistance would be less, owing to the increased area of actual contact; while, on the other hand, comparatively rough or uneven surfaces touching in two or three places would naturally tend to weld when a sufficient current passed. The strength of the current required to produce a given

* *Phil. Trans.*, 1889 A, p. 242.

Digitized by Google

apparent increase of the coefficient of friction would, therefore, depend very largely on the excellence of the mechanical fit. It is, of course, impossible that welding should take place while the sliding surfaces are in motion; but a small portion of the metal may be brought to a plastic state. This would tend to improve the accuracy of the contact by facilitating the wearing or the burning off of projections. A rapid sliding of the surfaces would in almost all cases, including that of the commutator and brushes of a motor, continually bring a fresh, and therefore a cooler mass of metal—say the commutator—in contact with the plastic part—say the brush. But the density of current with any decently-made brush should be far too small to give rise to any serious heating, and the natural wear affords the best facilities for a good fit.

The irregularity of the effect of the lubricant is not surprising when it is remembered that little or nothing was known about the ordinary action of lubricants until Mr. Tower made his well-known experiments on this important subject. It does not seem probable that the current which is employed for tramway work would often be heavy enough to produce any useful increase of adhesion, since, although the area of contact of the wheels with the rails is small, a new surface is being continually presented, offering a very different set of conditions to that of the sliding experiments of Mr. Schmidt.

THE EFFECT OF CIRCULAR MAGNETISATION ON THE RESISTANCE OF IRON.

BY HERBERT TOMLINSON, F.R.S.

It is now well known that the resistance of iron, nickel, cobalt, bismuth, and other metals, is increased by *longitudinal* magnetisation. Neither can there be any doubt that when a wire or rod of any of these metals carries a current, a magnetic field is created *circularly* around the wire, partly outside it, also partly inside it. The question has, therefore, naturally arisen, is the resistance which a wire of iron, nickel, cobalt, or bismuth offers to large currents different from the resistance which it offers to small currents? Before we attempt to answer this question let us examine the extent to which the resistance is affected by longitudinal magnetisation. In the accompanying table will be found some of the results obtained by the writer about ten years ago, a more detailed account of which can be obtained from the *Philosophical Transactions* for 1883, and the *Philosophical Magazine* for April, 1888.

Metal.	Condition.	Increase of resistance.* ΔR.	Magnetic susceptibility in C.-G.-S. units. κ.†	$\Delta R/\kappa$.
Iron	Annealed ...	23	30	0·8
Steel	Annealed ...	15	—	—
Steel	Very hard ...	0·7	—	—
Nickel ...	Annealed ...	81	9	9·0
Nickel ...	Unannealed	43	—	—
Cobalt ...	Unannealed	6	4	1·5
Bismuth...	Unannealed	0·2	−·000014	1500
Copper ...	Annealed ...	0‡	—	—

* In millionths, produced by 1 C.-G.-S. unit of magnetising force.

† The values of κ were determined for the same magnetising forces as those used for producing alteration of resistance. Within the limits of the experiments ΔR is roughly proportional to the force and also to κ.

‡ No change amounting to one in four millions could be detected with a magnetising force of 90 C.-G.-S. units.

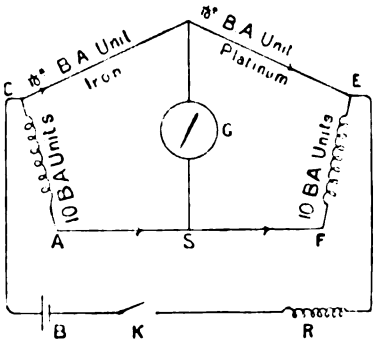
The numbers in the last three columns of the table refer to temporary magnetisation, *i.e.*, to the magnetisation which disappears on the removal of the magnetising force.

It will be noticed, in the first place, that the increase of resistance produced by unit force is in all cases *very minute*, so minute indeed that even with a force of 100 C.-G.-S. units the alteration of resistance of well-annealed nickel (the metal most affected by a force of given magnitude) would not amount to 1 per cent.

In the second place, it by no means follows that the metals which possess the greatest magnetic susceptibility are necessarily those which will be most affected in their resistance by a given force; the increase of resistance of nickel, for instance, being twice that of iron, whilst the susceptibility of the latter metal is more than three times that of the former.

It is, however, when we come to consider the last column that we meet with the most startling differences in the effects of magnetisation. The numbers in this column represent the increase of resistance which would be produced in each of the metals by magnetising them to such an extent that each cubic centimetre would possess unit magnetic moment. The effect of the magnetisation in this case would be twice as great for cobalt as for iron, twelve times as great for nickel, and about *two thousand* times as great for bismuth.

Though *longitudinal* magnetisation increases the resistance of iron to a comparatively small extent, yet, nevertheless, this increase is easily measurable with a good galvanometer; and did the circular magnetisation arising from the passage of a current through an iron wire produce results at all comparable with those produced by longitudinal magnetisation, we might reasonably expect to be able to detect them. Sir William Thomson has, however, shown that *transverse* magnetisation *decreases* the resistance of both iron and *nickel*; and though his experiments have been criticised by Beetz, who failed to obtain anything but negative results with transverse magnetisation, and attributed the decrease of resistance observed by Thomson to mere mechanical pull, the objection cannot well be sustained; for the writer has shown that not only would the alteration of resistance arising from the mechanical pull be too small, but also that this pull would produce *increase*, and not *decrease*, of resistance



in the case of *nickel*. Since, therefore, longitudinal magnetisation increased, and transverse magnetisation decreased, the resistance of iron, it still remained an open question as to what effect, if any, would be produced by circular magnetisation. The following arrangements (*see* illustration) were made by the writer for settling this point:—C D and D E are wires of well-annealed iron and platinum respectively, each of $\frac{1}{10}$th B-A. unit resistance. The diameter of the iron wire was exactly 1mm., and that of the platinum wire about 1mm.; the latter had, however, been drawn to such a gauge that the rise of temperature resulting from the passage of a current through it, caused very nearly the same increase of resistance in a given time as that caused by the same current in the iron; and thus, as a consequence, the current could be maintained for some minutes in both wires without very sensibly altering their resistance ratio. C A and E F are platinum-silver resistance coils, each of 10 B.-A. units. A F is a platinum-silver wire traversed by a sliding piece, S, which latter could, by a suitable spring and catch arrangement, be clamped to any part of the former; A F was extended over a scale divided into millimetres and having its zero in the centre. B is a Groves cell, K a key, R an adjustable resistance, and G a very sensitive reflecting galvanometer. It will be seen that the whole forms a Wheatstone's bridge arrangement, such that the main part of the current from B goes through the iron and platinum wires. The circuit of the galvanometer was always kept closed,* and the key K was only pressed down at each trial for a sufficient length of

* This should always be done when the alteration of resistance to be measured is very small, otherwise thermo-electrical currents may introduce serious error.

Digitized by Google

time (about 10 seconds) to enable the effects of self-induction to subside, and the observer to ascertain the correctness of the balance. The first attempt was made with resistances 3 B.-A. units and 0 in R alternately; and in order to avoid bias in the observations the sliding piece was after each change of resistance shifted from its position, and covered with a silk cloth, so that it could not be seen whilst it was being adjusted anew. The following readings were taken in this way:—

Resistance in R in B.-A. units.	Position of S when a balance was obtained.
3	57·0
0	58·0
3	56·0
0	55·5
3	55·0
0	54·0
Mean position of S for R=3	56·0
Ditto for R=0	55·8

Shifting the sliding piece through one division of the scale corresponded to an alteration of resistance of 3 in 100,000, the sliding piece was throughout to the *right* of the centre of the scale, so that for R = 0 the resistance of the iron *appeared* to be *less* than for R = 3 by 3 in 500,000.

A similar set of trials was made with R alternately 0 and 10 B.-A. units with very similar results. As the resistance of the battery and connecting wires had been determined it was possible to find the values of the currents through the iron and platinum. If we denote the resistance of the iron with the lowest current by unity, we have the following values for the resistance with the other currents.

Amperes traversing the Iron.	Resistance of the Iron.
0·2	1
0·5	1 - ·000026
2·0	1 - ·000033

The numbers in the second column do not differ from each other more than can be attributed to errors of observation. Such differences as do exist would appear to show that the *more powerful* the current the *less* the resistance, but other trials on subsequent days gave indications, equally slight, in the contrary direction. On the whole, the writer feels justified in assuming, from these and other experiments, that for *steady* currents ranging from ·1 to about 4 amperes, there is *certainly no difference in the resistance of an iron wire apart from that due to change of temperature amounting to one in twenty thousand.*

There is, however, another way of attacking the problem. It would seem to follow from the principle of conservation of energy that if the circular magnetisation, arising from the passage of a current through an iron wire, does produce any alteration in the resistance, this must be in the direction of increase. Now, longitudinal magnetisation would tend to annul circular magnetisation; consequently, if we keep the current through the iron constant and employ longitudinal magnetising forces, by means of a coil surrounding the wire, of gradually increasing amounts, such forces, if very feeble, should produce decrease of resistance in the wire traversed by the current and, if great, increase of resistance. The writer has tried the effect of changing the longitudinal magnetising force, whilst the current through the wire is kept constant, also of a constant longitudinal magnetising force with different current strengths through the wire; and after a very careful investigation, has come to the conclusion that the alteration of resistance produced by a longitudinal magnetising force is not *materially* affected by the strength of current traversing the iron. Of course it must be understood that the currents used, and the time that they are allowed to flow, must be such as not to materially increase the temperature of the wire, otherwise the mere alteration of susceptibility produced by alteration of temperature, will sensibly affect the increase of resistance produced by longitudinal magnetisation.

ELECTROLYTIC THEORIES.*

BY PROFESSOR G. F. FITZGERALD, F.R.S.

Electrolysis has been explained on two different theories by Grotthüs and Clausius. As generally received they differ. Grotthüs' theory, as generally given, assumes that the molecules in an electrolyte are both polarised and moved by the electric forces within the liquid. This seems so far untenable that it would appear that double the electric force would double both the polarisation and the motion of the molecules, and so should produce four times the electrolysis. The objection, however, assumes that we know the causes resisting the motion, and with proper, and not very improbable assumptions as to the resistance to motion depending on it and on the polarisation, a linear relation between current and electro-motive force, *i.e.*, obedience to Ohm's law, seems possible. A modification of Grotthüs' hypothesis in the direction of Clausius' is, however, possible. Suppose that when polarised the molecules *drew one another apart* at a rate proportional to the polarisation. This at once makes the relation between electric force and the decomposition a linear one, and so satisfies Ohm's law in the case of small currents. It also so far agrees with Clausius' hypothesis that it explains electrolysis and double decomposition as properties of the same kind. The molecules in a liquid will occasionally be arranged by accident in the proper polarised condition in a closed circuit for drawing one another apart; and if the circuit includes molecules of different kinds, there will result double decomposition. There seem to be very serious difficulties in supposing that uncombined atoms are for any finite time free in the liquid; and the supposition that it is a particular arrangement that is required before exchanges take place, and that with this arrangement exchanges take place of their own accord, seems to explain electrolysis and double decomposition without supposing free atoms to exist within the liquid. I have not assumed Prof. Armstrong's suggestion that the proper arrangement for double decomposition is a double molecule; but it seems a likely hypothesis, and one that should be investigated from the chemical rather than the physical side.

There are some other phenomena that have been explained upon the supposition that free atoms are gadding about in a liquid. Such are the lowering of the boiling and freezing points by solution of salts, and their effect on osmotic pressure. If dissociated atoms are going about in a liquid as in a gas, it seems impossible but that they must diffuse at different rates; and that this is not observed seems conclusive against the hypothesis, no matter what else the hypothesis may explain. Consider solution simply. Why does chloride of sodium dissolve in water? There must be some strong affinity between the two of a chemical or semi-chemical nature to break up the cohesion of the crystal; and it seems reasonable to assume that this same affinity keeps the molecules of NaCl moving about among the water molecules, so that they diffuse about. Now if the forces drawing them about be independent of the nature of the molecule, most of the phenomena explained by gaseous laws are explained. Pressure of a gas depends, at any temperature, on the number of molecules, and not on their kind. This is Avogadro's law, by which molecular weights are calculated; and if the forces drawing a molecule about in a liquid are independent of the kind of molecule, the very same law of pressure would hold, the pressure forward of molecules of different kinds would depend on their number only, and in the same way as Avogadro's law would enable molecular weights to be calculated. In this connection it is well to state that some bodies may, nevertheless, be much better able to produce pressure than others, because of their being more easily polarised, *i.e.*, turned into an effective direction. A molecule which could be easily turned into an effective direction would be about twice as effective as a molecule which went about in a higgledy-piggledy way; and one would consequently expect electrolytes to produce more, nearly double, the osmotic pressure that other bodies did. As to the changes of boiling and freezing points, they seem explicable by exactly the same hypothesis. The reduction of

* Communicated by the Secretaries of the Electrolysis Committee of the British Association.

Digitized by Google

vapour pressure by molecular affinity of dissolved salt would depend only on the number of molecules of salt if all salts have the same molecular affinity for water; and the same would apply to the change in freezing point. Hence all these phenomena are explained without assuming free atoms, and they are all explained by what can hardly avoid being a *vera causa*, namely, whatever affinities they are that cause solution, which latter is an unexplained phenomenon on the dissociation hypothesis. That it is reasonable to think that the forces keeping the molecules of salt moving about in the water are independent of the nature of the salt, appears from various considerations. In the first place, these forces are in all probability due to the residual affinities of the non-metallic elements. These same forces are probably the cause of crystallisation. These are old suggestions. That these residual affinities should be nearly the same for different combinations does not seem at all unlikely.

If a rather shaky argument in favour of its likelihood on mechanical grounds is desired, the following may deserve attention. Suppose a molecule of NaCl, for instance, at rest, or nearly so, in a crystal. Subject it to this affinity. Its velocity, after it has gone a distance, s, will be given by some such relation as $fs = \frac{1}{2} m v^2$. Now, for the sake of temperature equilibrium, with molecules of somewhat similar structure, $\frac{1}{2} m v^2$ must be the same in all. It seems likely that, at least approximately, the kinetic energy of motion is proportional to the total energy, and that this is the same for each molecular group; if so, the kinetic energy must be approximately the same for different groups. Now, with very dilute solutions s must be nearly the same for different molecules, and if so we get that for temperature equilibrium f must be independent of the nature of the molecule. How this equalisation of f for different kinds of molecules comes about may be as follows. Molecules in a liquid move about among one another, but are well within the sphere of one another's attraction, as is evidenced by superficial tension and by the tension to which a liquid can be subject. A very small change in the distance apart of the molecules means, however, a very great change in the forces between them, as otherwise they would be extensible and compressible like gases. It seems likely, then, that when a salt dissolves in a liquid it requires for temperature equilibrium that the distances of the molecules should change by the very small amount required in order that f may become the same for all substances. This very minute change in distance would not sensibly affect s.

NOTES ON THE DIFFERENCES BETWEEN ENGLISH AND AMERICAN ELECTRIC LIGHTING ACCESSORIES.*

Having had the advantage of gaining an intimate knowledge of the methods of construction and the electric lighting accessories in general use at the present time in England, I have naturally endeavoured to compare the ways and means that appear to have been generally adopted with those prevailing in England.

A comparison should not be made without due regard to the prevailing conditions, and I consider that the chief conditions are four in number:—

1. Climatic and characteristic differences. 2. The more general use of electric lighting in the States by the less moneyed classes. 3. That wiring work in the States is mostly done on a "centre distribution system." 4. The keen competition between the three or four leading companies in America.

As regards No. 1, an English electrician's first feeling is one of surprise that installations can be run at all; for, judging from first appearances, it would seem that very little trouble is taken to insure good insulation resistance and safety of the conductors. Wires seem to have been put up just in the quickest and easiest way, and little attention has been given to appearances; in fact, wires often sadly disfigure what would otherwise be called elegant rooms and buildings. Upon asking the reason, one is told that the American electrician "must hustle;" he has not time to "wait and look round;" he wants to get the work done and his account collected. The American is correct, and he is complying with natural conditions; for the American general public is not hard to please in the matter of appearance, and the ways and means are not questioned so long as the end is satisfactorily obtained. Climatic differences operate to a very large extent, and the methods adopted here, even if permitted on other grounds, would fail in England, on account of low insulation resistance.

2. As electric lighting here has come into general use among small stores, saloons, &c., a demand has arisen for cheap work, and artistic fittings are not required: while, owing to the dryness of the climate and the amount of wood used in the interior house construction, the cheap open cleat work with wires run in sight upon the varnished deal ceilings is quite a usual construction, and must evidently give satisfaction, both from the companies' and consumers' point of view. This condition has, I consider, had a great effect upon fittings and accessories, as tending rather to encourage inferior finish and construction, the idea being that low cost of production is all-important. In England we have not reached the time when power supply companies will instal the wires gratis, and the cost of current alone renders lighting a comparative luxury, so that all work is carried out in the better class of house or store, where the owner is prepared to pay a high price for its installation, and paying this price, he naturally becomes very exacting as to the appearance of the work and fittings. This condition, coupled with strict fire-office rules (almost as exacting, from the free American point of view), has combined to improve both the appearance, design, and construction of English accessories and installation work.

3. The "centre distribution" method of wiring seems to be preferred by American electricians, presumably because of the labour saved, as this system is easily and rapidly installed where the work is done on one floor, and long "runs" can be obtained and a conspicuous duplication of wires is no objection. It is urged that a more even potential is obtained by this method, but I believe only from an extra expenditure in copper, for in most cases the "free system" (general in England) gives just as even distribution with a smaller *total* weight of copper installed. The question here is whether copper is not cheaper than labour, for a free system requires additional labour in tapping on the many small distributing branches, and American labour being expensive, it is cheaper to work on a centre distribution system and pay for the extra weight of copper used. A centre distribution system also affects a saving in the number of branch and fuse blocks, not so many different sizes being called for in construction.

4. Owing to the keen and to a certain extent injurious competition existing between the leading companies (each of which has the only successful system) in the desire to bring out and perfect its main features, the details have to some extent been ignored or left to others to perfect or those adopted which have low first cost. Perfection in details can effect great savings in labour and petty annoyances, and often it is the apparently trivial improvements that make all the difference.

Wires.—As regards insulation, usage in America would seem to favour certain preparations and admixtures of rubber in preference to Para rubber, it being found that the dry air and heat have a withering effect on pure rubber, causing it to dry out and develop cracks.

An addition of certain well-known materials, such as sulphur, Trinidad pitch, &c., seems to have a beneficial effect and give a longer and more satisfactory life, while it affords an efficient insulation resistance. The dampness of the English atmosphere acts injuriously on a rubber composition, causing chemical changes and eventually destroying the necessary qualities of mechanical strength combined with insulation. A compromise has accordingly been made, and the construction now finding general favour is a thick coat of pure rubber on a tinned or cotton-coated copper wire, over which is served a double layer of cotton. A prepared rubber mixture is then applied, and this is served with a lapped or preferably braided coating of cotton. The wire is then passed through the vulcanising chamber and finished by being drawn through some tar compound. Positive wires are often soaked in a red lead compound, so that the colour will form a means of distinguishing them from the negatives, as in practice there are many cases when this difference in colour saves time and testing. I would mention that some users complain that the red wire is inferior to the black in point of life and insulation resistance.

The cables used in England for interior wiring work have an average insulation resistance from about 750 megohms (used in good dry positions, between joists, &c.). So 5,000 megohms per mile (used, say, for moulded work in plaster), and the corresponding small wires and leads, would vary from 150 to 500 megohms per mile.

American wire manufacturers do not appear to lay so much stress upon the actual tested electrical figures as upon the thickness of the insulation. To purchase wires according to the thickness of the insulation would be considered somewhat odd in England. But the American has an advantage over the English wire manufacturer inasmuch as he has not to carry such a large and varied stock of sizes; for, owing partly to experience and convenience on the one hand and fire-office restrictions on the other, no solid wires of

* Abstract of article by Fred. Bathurst, Assoc. Inst. E. E., in the *New York Electrical World*.

Digitized by Google

a larger diameter than No. 16 B.W.G. are being used in construction work, the required sectional area being obtained by stranding a number of fine wires (3, 7, 19, 37 are the numbers generally found in a strand); and a certain sectional area can either be obtained by stranding 7 wires, or 19 of a smaller diameter, which gives rise to a duplication of stock, for one contractor prefers 7 strands, another the 19 strand cable. Some six or eight different gauges are amply sufficient for ordinary work done on a "centre distribution" method, but many more are asked for when the "free distribution" is used.

Restrictions as to insulation resistance are far more rigid in England than here, for every building wired for electric light is tested, and must be approved by both the Company supplying the current, and the insuring fire officer, and all work must come up to a predetermined standard insulation resistance, usually

2·00	megohms	for a	25	-light	installation.
1·25	,,	,,	50	,,	,,
0·75	,,	,,	100	,,	,,
0·5	,,	,,	150	,,	,,

Here, although, of course, the better installations are tested for actual figures with a bridge and galvanometer. The magneto bell-test seems to be in pretty general use for ordinary work, and it is needless to say that only the roughest idea can be gained by this method, and the magneto only "speaks" when something is radically wrong. I have endeavoured to obtain actual figures for the open cleat-work prevalent here, but have not been able to collect sufficiently exact data to form a comparison. Any one having such figures would do well to publish them, as they would throw a great deal of light on the relative conditions of working.

Switches.—It is supposed that every electrician has at some period of his career improved, designed or invented an electric light switch, and consequently the class and type of the genus switch is legion, and the difficulty of making a comparison is greatly increased; but two or three general points of difference can be seen between English and American switches.

1. Double pole switches are used to a much greater extent here, and are evidently a step in the right direction. Even small 5 and 10 ampere switches are designed to break both poles at once, and in spite of the mechanical difficulty of making a small, neat, and efficient form of D. P. switch, American manufacturers have evidently tackled the problem seriously and obtained satisfactory results.

2. Switches that snap on and off are generally used here. While no one will question the advantage of the "snap off" and its partial elimination of the spark, the advantage of the "snap on" is not so apparent; it prevents children or others from "playing with" and "arcing" the switch so as to obtain the "pretty blue arc," which may possibly destroy the contact surfaces; but, on the other side, the mechanical construction to properly effect this object is imperfect, intricate, or clumsy. A good contact should be both a "grinding" and "sliding" one, and at present we have not this ideal in the "snap on" switch, for either the grinding (owing to the contact pressure) or the "sliding" and cleaning action is only partially carried out.

The mechanical devices finding general favour here are either "cam movements" or "springs working over centres."

3. Place an English type of switch beside the American, and a glance shows a striking difference. The English one only attempts one-half what the American does, but has all the advantage in the matter of appearance, for it seems to have been well designed, with the fewest number of working parts, and has a solid, substantial look about it. The American, on the contrary, seems to contain many small parts, roughly finished and hastily put together, and has evidently had little hand work put on it. Perhaps it is unfair to compare two articles that do not accomplish exactly the same objects, but the illustration will serve to point out the noticeable point that in the English switch considerable attention has evidently been given to appearance.

4. In the smaller switches two sizes seem to be all that are required; while in England 3, 5, 10, 15, and 20 ampere switches are in general use.

Here switch socket holders are provided for nearly every lamp, while in English installation the switch for the room can nearly always be found just by the door, so that any one entering in the dark can immediately light up the room without groping about for the fitting.

5. Many switches seem still to be fitted with wood bases, although generally provided with mica "flash plates." Dry wood is a very efficient insulator, easy to obtain and convenient to work, but is extremely liable to fire. In England slate or porcelain is in general use. Slate, when boiled in paraffin, after having been carefully selected, is fairly reliable, but some slates are far more absorbent than others, and slates from the same quarry often vary greatly in insulation resistance. English porcelain is a very satisfactory material for switch bases.

Fixtures.—In America the gas fixtures are generally used for the attachment of electric lamps and globes, and in England their use is the exception; for owing to the general use of gas the centre of a room is usually occupied by the conventional gas fixture, which, while difficult to adapt, is still more difficult to insulate from earth, and fire officers discountenance the combination. The electrician, therefore, takes to the walls, and by putting in small ornamental brackets or pendant brackets, secures a more even distribution of light with a prettier effect. People using electricity expect more light than from gas, and look for something out of the ordinary, and a tendency has thus arisen to make electric fixtures as different in design as possible from gas fixtures.

American fixtures are generally made with "galleries" for carrying the shade; in England shade-carrying holders are used on account of their being more compact and better and generally superior in appearance.

Lampholders.—A peculiar point of difference is apparent in the respective lampholders or sockets.

Here nearly all are designed upon the plan of having an inner central contact plate surrounded by an outer contact ring suitably insulated from it, and the lamp with cap to suit is either screwed or forced up into the socket. The usual English holder has two contact pillars which are mounted side by side on an insulating base. The pillars have spring contact plungers and make contact on two half-moon plates embedded in the lamp cap; the cap is fitted with small outside pins which engage in bayonet slots. This construction, although, perhaps, slightly more expensive to manufacture than the former, has one or two good points: first, that there is a greater certainty of contact, as the quarter turn (securing the pins in the bayonet slots) gives a rubbing and cleaning action while pressure is applied from the contact plungers; second, there is no tendency to overtwist and break a lamp while inserting it, for the "snap" indicates when the lamp is securely fixed; there is also little chance of a lamp falling out of the socket.

Owing to the almost exclusive use here of switch socket-holders, fixtures have to be placed within easy reach, and are sometimes awkwardly low. The tap or switch-handle makes a shade-carrier on the socket inconvenient, and a gallery preferable. A closed gallery looks heavy and clumsy, while an open one allows dust to collect on the lamp bulb. The English shade-carrying holder is designed to take a shade with a 1⅛in. diameter hole, and the sliding sleeve fits the hole exactly, so that by its use a more graceful combination can be made, and the disadvantages of the gallery excluded.

Lamps.—The monopoly of the lamp industry in England is a sore point with electricians, as having caused users of incandescent lamps disgust and annoyance in various ways, and prevented long-looked-for improvements in efficiency.

Fuse and Branch Blocks.—Some four or five sizes of branch blocks seem sufficient to fill all conditions arising in American construction work, mainly for the reason given under condition No. 3. In England the branch block used here is unknown, because it is not applicable (at any rate from an artistic point of view) to moulding work, its place being filled by two or three patented devices used in conjunction with a large number of fuse boxes. American and English porcelain are very different; the former is vitreous. English porcelain is an earthenware. Its name arises from the fact of its superior white colour and perfect glaze. English porcelain is undoubtedly much easier to work than American, and gives more highly finished work, is not so brittle, and there is no material difference in specific resistance. In these highly insulating materials surface conduction is of greater importance than the slight interior conduction.

The design of main cut-outs and double pole-casing pattern safety junctions is virtually the same, the only difference being that in American practice there is a tendency to clamp the cable between two plain longitudinal surfaces in preference to passing it around a screw head under a washer. English practice is to cover up entirely if possible all metal parts on branch blocks, ceiling roses, fuses, &c., so that there is no possibility of obtaining a shock accidentally. Americans do not seem very particular in this respect. In England magnetic cut-outs have proved very reliable. There must be an excellent opening in the American market for them.

Ceiling Roses.—The American ceiling rose is not an artistic addition to a room, for the reason that some metallic part is uncovered, from the fact that the feeding wire is connected up by clamping it in a jaw or similar device which must stand away from the base. This device, while facilitating erection, would not be permitted in England, where all connections of this sort are made by soldering on a small piece of wire, and bringing the insulation completely within the base.

As the main features of the different systems become better known, and the chief electrical problems solved, more and more attention is being bestowed on the minor accessories, and the system possessing the most carefully worked-out details must eventually secure the lead.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 5 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

RAILWAY RATES.

The draft classification of merchandise traffic and a schedule of rates and charges, being the result of the protracted enquiry which was held before Lord BALFOUR OF BURLEIGH and Mr. COURTENAY BOYLE, has been issued by the Railway Department of the Board of Trade. Five separate copies are printed for the five principal railway companies; but we have found on a careful examination that in so far as they concern the electrical trades, these are identical. When this important matter was first brought before the Electrical Trades Section of the London Chamber of Commerce, we printed at length long list (*The Electrician*, May 17th, 1889) of all the items that could possibly concern the electrical industry. These were extracted from a schedule deposited by the Railway Companies' Association with the Board of Trade. The matter was at once taken up, and a committee was appointed, on which it is no secret that Mr. GARCKE did all the work. The articles marked for objection are given in another column.

Thanks to the organisation of the London Chamber of Commerce, the objections were dealt with in a systematic form by a firm of solicitors. The classification, as most of our readers are aware, consists of eight classes—A, B, C, 1, 2, 3, 4, 5, A being the lowest rate, and comprising coal and ore, &c., in four-ton lots, and 5 the highest, for expensive or fragile goods. On the objection forms for each item were given (1) the class proposed by the Companies in the Deposited Schedule; (2) the class proposed by the objector; (3) the class in the Clearing House classification. The objections were set out, and reasons were given for the objections of the traders. These were sent to the Companies, who appended a

Digitized by Google

reply to each, either defending their claims or conceding the classification proposed by the objectors. A most careful watch had to be kept for tricks. We impute no fraud whatever, or even shabbiness; but there are tricks in every trade, which are recognised by a certain code of morality as tricks.

A case in point was that of "telegraph insulators." These were Class 1 in the Clearing House list, and were omitted in the Deposited Schedule. The Chamber of Commerce objected to the omission, since, not being specifically mentioned under any other class, they would be liable to be charged at the highest rate as Class 5. The Companies' reply was that these were covered by the wider term "electric" insulators; and added, "There is no reason why 'telegraph' insulators should be classed lower than 'electric' insulators, as some of the telegraph insulators are of very considerable value." Now, no objection had been taken to "electric insulators" in Class 2, as it is difficult to say what the term means, and having lodged no objection, there might have been a technical difficulty in dealing with the matter. But the inquiry was conducted in so careful and impartial a manner that every facility was given for explanation and definition, and in this case the Board of Trade recommend that "telegraph insulators, earthenware packed," should be in Class 1, and electric insulators in Class 2. The curious distinction between "electric storage batteries" placed in Class 3, and "electric accumulators" in Class 2 as given in the Deposited Schedule, was not supported by the Companies; the latter description and class only are adopted. We need not recapitulate the arguments which were made at the inquiry on the other items, as the proceedings were reported more or less fully in our columns at the time. The objections to omission drew from the Companies definitions and classifications, as, for example, the important article "dynamos," which it is decided goes as "machinery," and the unimportant "sponge cloth" which will go as "cotton and linen goods," but which, had it not been for the objection, might have had to go under "millinery" or "sponges" in Class 5.

On the whole, the electrical trade is to be congratulated on the result of the inquiry, and they have to thank the Chamber of Commerce, where a special staff was engaged under Mr. Musgrave, who worked at nothing else for months. It is rather remarkable that so little interest was taken in the matter by the electrical trade generally, and still more singular was the complete indifference of certain other trades, who either failed to give sufficient instruction to their representatives, or in some cases neglected to put in any appearance. In one or two cases, such as those relating to iron and steel castings, sheets, &c., it was considered that the electrical trade would be safe if the matter were left in the hands of others; but the results are not very satisfactory.

"Castings (iron or steel) light, in boxes, cases, crates, casks, or hampers" were proposed for Class 1; but they are placed in Class 2. Perhaps that is fair, but "castings, steel e.o.h.p., that is "except otherwise hereinbefore specified," are placed by the Board of Trade in Class 3, together with "castings, iron, light, e.o.h.p." We find no mention of the important item of sheet iron, except in Class B, which is for consignments of four tons and upwards. The Companies agreed to adopt Class 1, as proposed by the Chamber of Commerce. Nor do iron telegraph poles appear except in Class B. The two most successful results of the objections raised by the electrical trades, if the classification of dynamos, which was a formal matter, be excepted, were "telegraph cable" and cotton-covered wire. The Companies asserted that the former was "frequently coiled on to the waggons and uncoiled for delivery." They were unable to give a single instance when challenged to do so; and the Class 3 which was asked for has been granted by the Board of Trade. Cotton-covered wire, which no electrician can dispense with, was placed in the deposited schedule in Class 4; but Class 2 was allowed, since it is a raw material, and but little liable to damage, It would have been impossible to have carried these points without the assistance of the London Chamber of Commerce, unless a special association or committee had been formed for the purpose, and this would have entailed upon its members a great deal of work which is a matter of routine with the organisation which is so ably headed by Mr. Kenric Murray. Those firms who have not joined the Chamber will reap the benefits of its work, and they may without much difficulty reckon the amount which they will save under the proposed classification. This should be an inducement to support an association which is weak merely in the number of those who attend the meetings, and which may any day have to cope with matters even more important to the electrical trades than are these Railway Rates.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

(Continued from page 353.)

§ 9. **Transformer Station at Leghorn (Livorno).**—At Leghorn there is a central station in the Via Costanza, on the same general plan as that at Rome, for distribution of electric energy by means of transformers. The plant was constructed by Ganz, and the machines and regulating apparatus are similar in general design to that described in the foregoing sections. A general view of the machine-room is given in Fig. 28. There are at present (1890) three combined engines and dynamos in position. The engines are direct-acting, high-pressure single-cylinder engines of 150 horse-power, fitted with centrifugal spring governors, the governor wheels forming also the pulley by means of which the excitors are driven. These engines are coupled direct to Ganz alternators of the A type, similar in design to those at Rome. The alternators furnish at maximum load a current of 40 amperes at 2,000 volts, and are therefore 80 kilowatt machines. The dynamos are driven at a speed of 250 revolutions per minute. The armatures have 20 fixed bobbins, and the revolving field-magnets 20 bobbins; hence the current has 5,000 alternations per minute, or 42 complete periods. The armature frame rests on a massive bed-plate, on which is also erected the engine; and the arrangement of slotted bed-plate and screw before described renders it possible to traverse the armature away from the field-magnet, and get at it for repairs. Both the field-magnet cores and the armature coil cores are built up of laminated iron plates. There are three such steam dynamos placed side by side; they take steam from a battery of three Babcock and Wilcox water-tube boilers, each of 150 horse-power size.

The excitors are driven off the governor wheel of each engine, and each furnish an exciting current of 25 amperes, at an E.M.F. of 100 volts.

The alternating current furnished by the dynamos is employed to feed about 2,000 incandescent lamps of 16 candle-power. From the station proceed two primary circuits, each consisting of a pair of insulated overhead copper conductors of 28 square millimetres in cross sectional area. The primary current supplies 17 transformers of 7·5 kilowatt size, four of 3·75 kilowatt size, and one of 1·875 kilowatt size, having their primary circuits arranged as usual in parallel between the primary mains. Although the station is not a large one, it is interesting from the fact that the alternators are worked in parallel on a single primary circuit as a regular thing. The two primary circuits start from a switchboard, which is exceedingly well

* All rights are reserved.

Digitized by Google

arranged. The various connections on it are all made by highly insulated rubber-covered copper wire, carried on porcelain insulators, and the switches, cut-outs, &c, are all on porcelain bases, and have porcelain handles or covers. At one side of the switchboard (*see* Fig. 28) is a bank of 1,320 incandescent lamps. The usual voltmeters, amperemeters, and regulators, are conveniently placed. The automatic mercury cup resistance described in a previous section is also employed to maintain a constant potential at some point on the primary circuit, irrespective of the outgoing current. Each dynamo and engine can carry a load of about 1,200 16 candle-power lamps. When, therefore, the load on the external circuits does not exceed this, or equivalent to about a primary current of 30 amperes, the two separate primary currents are worked as one circuit on one machine. After midnight, when the load generally falls to less than 300 lamps, it is taken over by a small auto-excited alternator, worked by a separate small engine. When, however, the demand exceeds 1,000—1,100

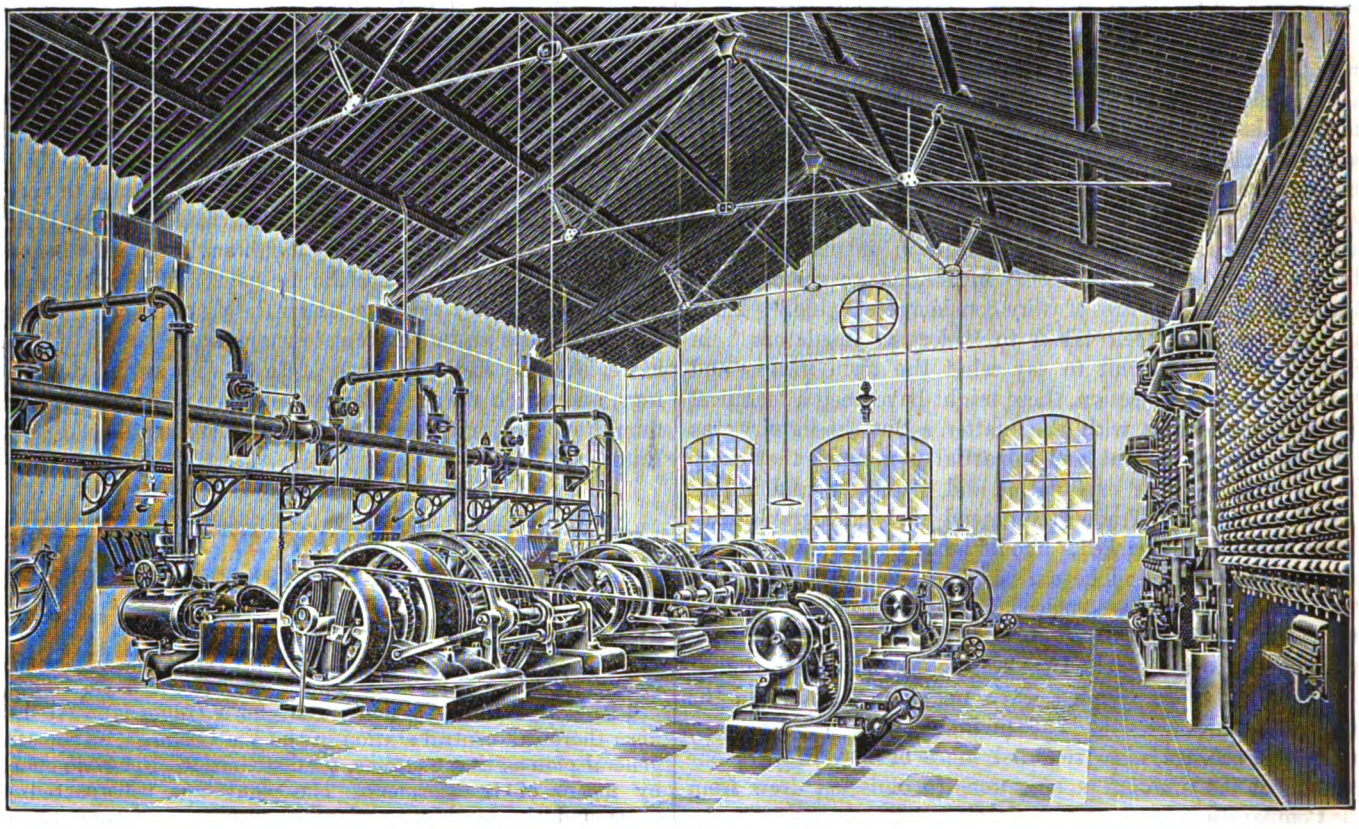

FIG. 28.—View of Central Station, Leghorn.

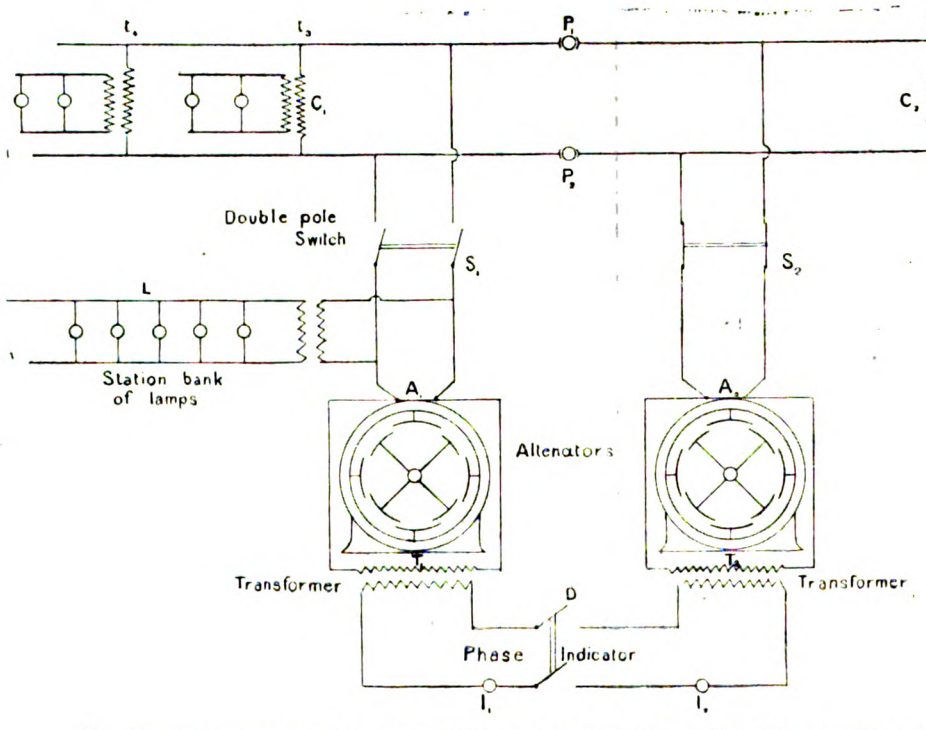

FIG. 29.—Diagram representing phase-indicating arrangement for putting alternators in parallel on one united circuit.

Digitized by Google

lamps, two of the larger machines are worked in parallel on to the two primary circuits joined into one. The method by which this parallel working of the alternators is practically carried out is very simple. Let C_1 and C_2 (Fig. 29) be the two separate primary circuits, which may be supposed to be joined into one circuit by the plugs P_1 P_2. Let one alternator, A_2, be supposed to be working on this single circuit, and that the time has come when a second alternator, A_1, has to be added in parallel with the first one to support the lamp load.

The first step is to run up the alternator A_1 to the proper speed and to set it to work on the station bank of lamps L and adjust its E.M.F., so that it has the same electromotive force and current output as the dynamo A_2 already on the circuit. From the poles of each alternator proceed leads to a pair of transformers T_1 T_2 whose secondaries are joined in series through a couple of incandescent lamps l_1 l_2. On closing the double pole switch D the transformers T_1 and T_2 work together on the pair of lamps; and according as the alternators A_1 A_2 are in similar or in opposite phase as regards electromotive force, so are the lamps l_1 l_2 extinguished or alight. The moment when the lamps l_1 l_2 are both out the two machines A_1 A_2 are in step, although on different circuits. As the machines pass out of step the lamps l_1 l_2 pulsate in brightness, producing luminous "beats" as the current pulses catch each other up. At the instant when the indicating lamps are not visibly luminous the double pole switch S_1 is closed. The dynamo A_2 is then in parallel with A_1 on the circuit C_1 C_2; the load of lamps on L is then removed little by little and the two alternators A_1 and A_2 are finally left working on one circuit. Similar arrangements allow all three dynamos to be put in parallel. At Leghorn it is found to be very easy to throw in one, two, or three alternators in parallel as the lamp-load varies, and the machines keep each other in step perfectly when once they are put in parallel.

The station, as will be seen from the view in Fig. 28, is a one-story building, and consists of two rooms, one the boiler-house, and the other the dynamo-room. The station was opened in October, 1889, and has been in successful operation ever since. The station covers an area of about 45ft. by 100ft., and the present building can accommodate one more 150 horse-power engine, boiler, and dynamo, having, therefore, a capacity when full for three active dynamos and one reserve, or an effective output of 240 kilowatts, or 4,000 16 candle-power lamps in full use and for about 6,000 such lamps installed. This station is exceedingly well arranged; and as an example of alternators worked regularly in parallel is an interesting illustration of theory carried out into effective practice.

(To be continued.)

THE KENSINGTON COURT STATION.

The fact that the current has only once been off the mains of this station since the start was made in 1887 cannot but inspire a feeling of confidence in the steady supply which is provided in this district. It will be remembered that not long after the station was started a steam-pipe burst, and the attendant lost his nerve. The dynamos were stopped, and the supply carried on by the accumulators. An amperemeter which happened to be in the battery circuit was destroyed by the large current passing through it; but this did not extinguish the circuits beyond one minute, the attendant having only to turn a switch to cut out the amperemeter, the most noticeable defect being the fall of pressure below the standard amount after the accumulators had been at work for some time. The whole affair did not last more than three-quarters of an hour, during half an hour of which the E.M.F. supplied was 10 to 15 per cent. below the 100 volts. As this, the sole case, happened in the afternoon, very few persons were aware of the stoppage; and so, as far as the supply company is concerned, the consumers have been practically free from those annoying accidents or mismanagements by which the lights of most other supply companies in London have been extinguished from time to time; and those sudden blinkings due to changing over, which many station attendants believe are quite unnoticed, are here unknown. The old engine-room at Kensington Court is hardly to be recognised, it having been thrown into the fine building which now contains the machinery. Three Babcox-Wilcox boilers, each of 250 horse-power, with double steam drums, are placed at the back, behind a partition, which keeps the rest of the room clean and cool. Two of these are under steam at a time, and work at 150lbs. pressure. Four Willans and Robinson 200 horse-power central valve compound engines occupy the middle of the floor, and to two of these are coupled Crompton shunt-wound dynamos of an output of 120,000 watts. Besides these are three 90 horse-power smaller engines and dynamos of 55,000 watts output. The principal switch-board is placed in a gallery, and is of a very complete character, providing for every possible combination of connection with the dynamos, batteries, and mains. One large and two of the smaller dynamos were at work when we visited the station at about half-past ten on Friday last. The engines for silence, and the dynamos for sparkless collection and coolness, were all that could be desired. Two of the larger engines are now awaiting their dynamos. When these are in place, the plant will be sufficient to supply 30,000 lamps. At present there are 19,000 lamps on ten miles of mains of the two Kensington and Knightsbridge stations. The greater part of the new batteries are on the first floor, and are arranged in a very substantial manner. There is, in addition, a battery station in the Queen's Gate district, about half-a-mile from the Kensington Court station. This is principally used as a reserve and transformer station in connection with the Kensington Court station, from which the two large batteries are charged in series, and discharged on to the three-wire system. In a small room a number of meters are being tested, some of them being apparently more ingenious than trustworthy.

The Aron meter is the one in general use, and it gives satisfaction to both parties. It is found in winter that the aggregate amount of current registered by the house meters throughout the district agrees within five per cent. with the main current as measured in the station, a result which few, if any, gas works or waterworks can show, and which has, as far as we are aware, been unapproached by any electric supply station. The Aron meters are not sent out in the condition in which they are received, as has been done by other companies, but they are carefully timed for a fortnight at the station, and then tested with the current. They are then timed for two or three days in position in the consumer's house. Final adjustment is sometimes found to be required. One highly ingenious meter contains an electric clock, in whose works certain springs are liable to go wrong. One of these having been put up in a house, the inhabitants were aroused in the middle of the night by an alarming knocking and rattle which proceeded from the meter, which is said to have made sleep impossible.

Scoffers have averred that since the current is always on the line the engineers cannot know the insulation resistance of the mains. The method of testing is as follows:—At frequent intervals during the day and night the ends of the mains in the station are put to earth through an 8 candle-power lamp. If the lamp glows perceptibly, it is known that there is a leak of a fraction of an ampere on one main; if it glows brightly, there is a more serious leak. At a quiet time of day, either at about noon or at about four o'clock in the morning, the current is turned off the particular main for an instant, and a rough localising test is made. Then the testers proceed to the nearest junction box, and another test is made. It is necessary in rare cases to give notice to two or three houses that the current must be shut off for a few moments to make a test; but, as a rule, the engineers have no difficulty in finding the right house. The leaks are due sometimes to bad wiring, or to accidental overflow of water, or occasionally to some tampering with the wires. Experience has shown that leaks do not develope suddenly, and allow the main fuse to go, as suggested by Mr. Mordey in the discussion on Major Cardew's recent Paper. On the contrary, it is very rare to find a main fuse melted, unless a meddling butler tries to manipulate the mains with a pair of pliers, when he finds that there is plenty of time to

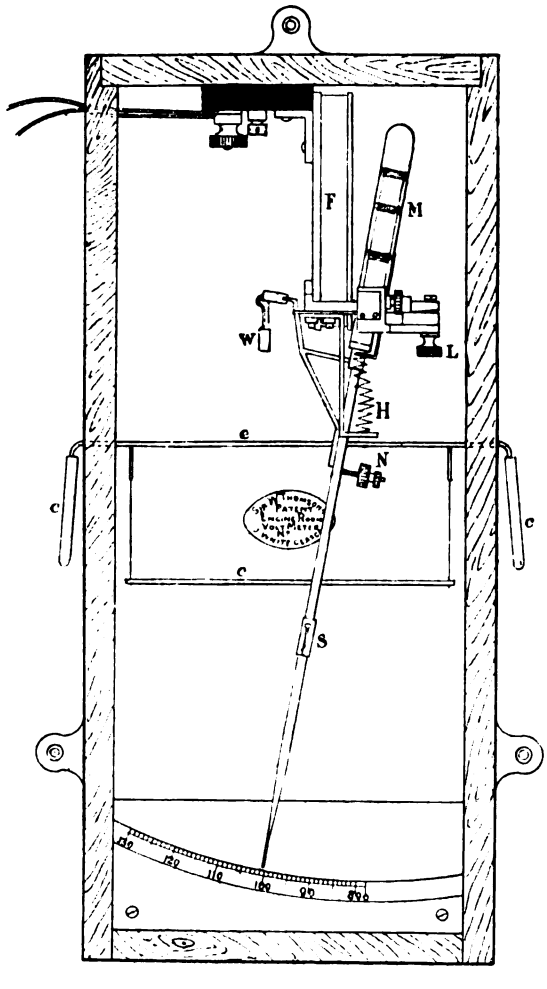
Digitized by Google

burn his fingers before the cut-out has acted. This individual takes so great an interest in the electric lighting, that he carefully takes out all the cut-outs (of the screw plug pattern) before a dinner party, and smartens them up, and then with less care replaces them in the wrong holes. The supply company is, of course, blamed when the lamps light up for an instant and then cease to burn.

In pushing our inquiries on the subject of leaks, we learned that a lead-covered cable, on which no leak existed that could be detected by the lamp test, suddenly broke down, and on examination it was found that the cable which was imbedded in brickwork had been earthed through a high resistance, and an electrolytic action, which had evidently gone on for several months, had eaten away the conductor. The fault lies in using and relying on lead-covered cables which may be called of the "dry insulation pattern"—that is, the insulation only remains good as long as the lead is perfect; but if water gets through the lead cover, the insulation slowly breaks down. Luckily this defect was soon found out, and very little of this kind of cable has been used. These accidents, however, are very rare, and there are not yet enough on record to enable any particular conclusions to be drawn from them.

SIR WILLIAM THOMSON'S NEW ENGINE-ROOM VOLTMETER.

Sir William Thomson's new engine-room voltmeter is intended for installation work on either direct or alternating circuits,



where it is convenient to have a direct-reading voltmeter with large scale divisions. The instrument, as shown in the figure, depends for its action upon the repulsion of a movable coil, M, by a fixed coil, F. The fixed coil, F, bears all the other portions of the instrument attached to it, and is in its turn supported from a vulcanite block fixed to the instrument case. This vulcanite block also bears the terminals of the instrument. The movable coil is supported on knife edges, and the circuit through it from the fixed coil of the voltmeter is made by two spirals of fine copper wire. A pointer attached to the movable coil indicates by direct readings in volts the difference of potential between the terminals of the instrument. Attached to the pointer on one side, and perpendicular to it, is a short arm, with a screw nut, N, which, together with the sliding weight, S, on the pointer, serves to adjust the balance of the movable parts. To the other side of the pointer is attached a bracketed arm terminating in a knife-edged stirrup, on which is hung the weight, W, fixing the constant of the instrument. The movable coil can be lifted from its bearings by turning the screw, L, which raises a lever passing below the knife-edge trunnions, and so fixes the movable portion of the instrument when the instrument is being removed from place to place, or is packed for carriage. A checker, *c c*, is provided to facilitate the taking of readings when the circuit is for some reason being made and broken, or the potential being suddenly and largely varied.

The instrument is graduated by direct comparison with a standard centi-ampere balance. The movable portion is first adjusted to be in neutral equilibrium by means of the sliding weight, S, and the nut, N; the weight, W, is then hung on the knife-edged stirrup. This weight causes the pointer to come to zero, in which position the movable coil is pressed against the fixed one. The scale consists of very nearly equal divisions, and is usually graduated from 80 or 90 to 140 or 150 milliamperes. The coils of the instrument are wound with many turns of copper wire, and have a total resistance of about 100 ohms. An anti-inductive resistance of platinoid wire, fixed to the back of the instrument, is adjusted to make up with the resistance of the coils 1,000 ohms at a given specified temperature; thus, as the scale is in milliamperes, the instrument reads directly in volts.

THE WORKING EFFICIENCY OF SECONDARY CELLS.*

By W. E. Ayrton, C. G. Lamb, E. W. Smith, and M. W. Woods, Associates.

(Concluded from page 347.)

IX.—*Resistance.*

The resistance in ohms of an accumulator when charging and discharging is given respectively by

$$\frac{V-E}{A}, \text{ and } \frac{E-V}{A},$$

where V is the potential difference in volts at the terminals when a current of A amperes is passing, and E is the E.M.F. of the accumulator at the moment V is measured. To measure E the main circuit is broken, and the potential difference observed as quickly as possible. On breaking the circuit, however, the deflection of the voltmeter does not sharply change from the value that measured V to another definite value that measures E; but, on the contrary, as seen from Fig. 4, in consequence of the fall of the E.M.F. of an accumulator on breaking the charging circuit, and in consequence of a similar rise in the E.M.F. on breaking the discharging circuit, the voltmeter deflection continues to vary for several minutes after the circuit is broken. Hence the value of E, measured by a voltmeter which is not infinitely dead-beat, must be too small during charging, and too large during discharging; and consequently, since the above formulæ for the resistance are only true when V and E are the simultaneous values of the potential density at the terminals of the accumulator and of its E.M.F., it follows that the resistance has hitherto been measured too large both in charging and discharging.

The magnitude of the error that has been thus made in different experiments depends, of course, on how dead-beat a voltmeter was employed, and, consequently, on how long a time was allowed to elapse between the breaking of the main circuit and the taking of the reading. For example, we find that towards the end of the charge with the normal current of 9 amperes the E.M.F. varies about one per cent. in 20 seconds after the circuit is opened. Now, as the difference between V and E which measures

* Read at the Extraordinary General Meeting of the Institution of Electrical Engineers at Edinburgh, on July 16th, 1890.

Digitized by Google

the resistance, is only of the order 0·1 volt when it has its maximum value during the normal charge or discharge,—that is, of the order four per cent. of E—it follows that an error of one per cent. in the measurement of E would make an error of about 25 per cent. in the measurement of the resistance.

To measure the resistance accurately we ought to be able to measure the difference between V and E to one-thousandth of a volt, and, therefore, as E is about two volts, the voltmeter must be very sensitive with a long, open, scale, and the needle must move through a considerable angle; whereas, in consequence of the rapid variation in E, the voltmeter must be very dead-beat—a condition almost incompatible with a long range and great sensibility.

These two conditions, however, we have fulfilled by the employment of the following device, by means of which the difference between the values of V and of E was measured to the one-thousandth of a volt at identically the same moment that the values of V and A were measured. The process was as follows:—

1st. The sensibility of the voltmeter was adjusted so that 12 volts produced a deflection of 600 divisions, and V, the potential difference at the terminals of the four accumulators under test, was measured.

2nd. A compensating E.M.F. was introduced into the circuit just sufficient to bring the spot of light to zero.

3rd. The sensibility of the voltmeter was increased 60 times.

4th. The main circuit was broken, and the time variation of E, the E.M.F. of the accumulators under test, observed by noting the position of the spot of light at the successive ticks of a metronome, whose rate of going was before each experiment carefully adjusted by comparing the metronome with a chronometer.

5th. A time curve for the values of E was drawn, and by producing it back until it cut the line passing through time 0—that is, the time when the main circuit was broken—we obtained the value of E at the same moment that the values of V and A were measured.

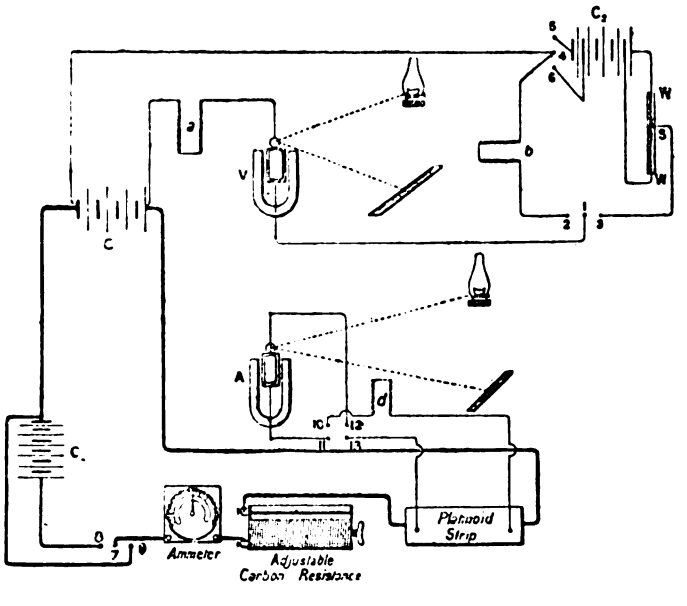


FIG. 10.

The apparatus employed is symbolically shown in Fig. 10. C_1 are the four accumulators under test; when they were being charged by means of the accumulators C_2, a bridge-piece was placed so as to join the mercury cups 7 and 8; whereas, when C_1 were being discharged, mercury cup 7 was joined to 9 instead of to 8. In both cases the current passed along the thick lines through an A. and P. magnifying spring ammeter, whose indications furnished an approximate measure of the current, through an adjustable carbon resistance and a platinoid strip which could carry the maximum current, 10 amperes, used in these tests, without its resistance being perceptibly altered. To two points of this strip were soldered two wires going to the mercury cups 10 and 13; these were joined respectively to 11 and 12 in charging, and to 12 and 11 in discharging, so that the current always went through the D'Arsonval galvanometer A in the same direction. This galvanometer then measured the charging or discharging current, its sensibility being such that for a current of 9 amperes passing through the circuit a deflection of 600 scale divisions was produced when the resistance in d was 185 ohms, that of the galvanometer A itself being 52 ohms.

By joining the mercury cups 1 and 2 with a bridge-piece, the potential difference between the terminals of the accumulators under test, C_1, could be measured with the voltmeter V; the sensibility being such that with a resistance of 791 ohms in a, and 63,696 ohms in b, a deflection of 600 scale divisions corresponded with a potential difference of 12 volts. By connecting the mercury cup 1 with 3 instead of with 2, the resistance b was cut out of the circuit, and the sensibility of the voltmeter V was increased 60 times. If now 4 were connected with 5 or with 6, and the sliding contact S moved along the thick wire WW, a point could be found such that no current passed through the voltmeter V. Next, the main circuit indicated by the thick wires was broken, when the spot of light would move quickly across a portion of the scale, and then continue moving right across the rest of the scale. The first part of this motion was of course due to the sudden variation of the potential difference at the terminals of the accumulators C_1 on the current through them being stopped, while the continuation of the motion was due to the subsequent variation of the E.M.F. of these accumulators after the current was stopped. And the value of the E.M.F. at any moment was equal to

$$V \pm \frac{0{\cdot}2\,d}{600},$$

where d was the deflection of the voltmeter spot of light at the moment in question, and V was the potential difference between the terminals of the cells C_1 just before the main circuit was broken, and which was measured by the voltmeter deflection when mercury cup 1 was connected with 2. In discharging the + sign was, of course, used, and in charging the — sign.

This potential difference at the terminals of the four accumulators under test, C_1, and which had to be balanced by the E.M.F. of the accumulators C_2, approached 9·6 volts towards the end of a charge, while it fell to 7·6 volts at the end of a discharge. In the former case the E.M.F. of four cells and a portion of the fifth of the compensating accumulators C_2 was employed, while in the latter the E.M.F. of three and a portion of the fourth sufficed. Hence, during the charge mercury cups 4 and 5 were connected together, while during the discharge it was 4 and 6 that were connected together. The portion of the E.M.F. of the last of the compensating cells was, as shown in the figure, obtained by shunting this cell through a platinoid wire, WW, of about 2 ohms resistance, and making contact with a point of this wire farther from, or nearer to, the positive pole of this cell. This adjustment of the position of S caused very little change in the resistance of the voltmeter circuit, because the resistance of WW was but a small portion of the entire resistance in the voltmeter circuit.

This method of measuring the resistance of accumulators was applied by three of the students of the Central Institution—Messrs. Müller, Stephens, and Wightman—to determine the variation of the resistance during the entire discharge of the cells with 10 amperes, and charge with 9; further, during May and June of this year Mr. Müller has, with great perseverance, been making an uninterrupted series of observations, day and night, to determine the resistance during the entire discharge and charge for various currents. For each of these currents the cells are being brought to a steady working state by many discharges and charges being successively and without interruption made with each current. In the case of the small current the time of a charge and discharge is tediously long, the charge, for example, with three amperes requiring 40 hours to raise the potential difference from 1·9 to 2·4 volts per cell, so that several weeks have to be spent obtaining the resistance for this current. This investigation of resistance is not yet completed, and therefore we do not propose in this Paper to refer to the variation of the resistance of a cell with different currents when the cell is brought to a steady working state for each current. Such an experiment has not, as far as we are aware, ever before been attempted with accumulators, former observers having contented themselves with merely observing the variation of the resistance when the current during discharge or charge was abruptly changed from one value to another. This is a very different thing from ascertaining how the resistance of an accumulator varies with the current when each of the different currents employed is steadily used for some weeks in the discharging and charging of the cell, until the cell has arrived at a steady working state for the current in question.

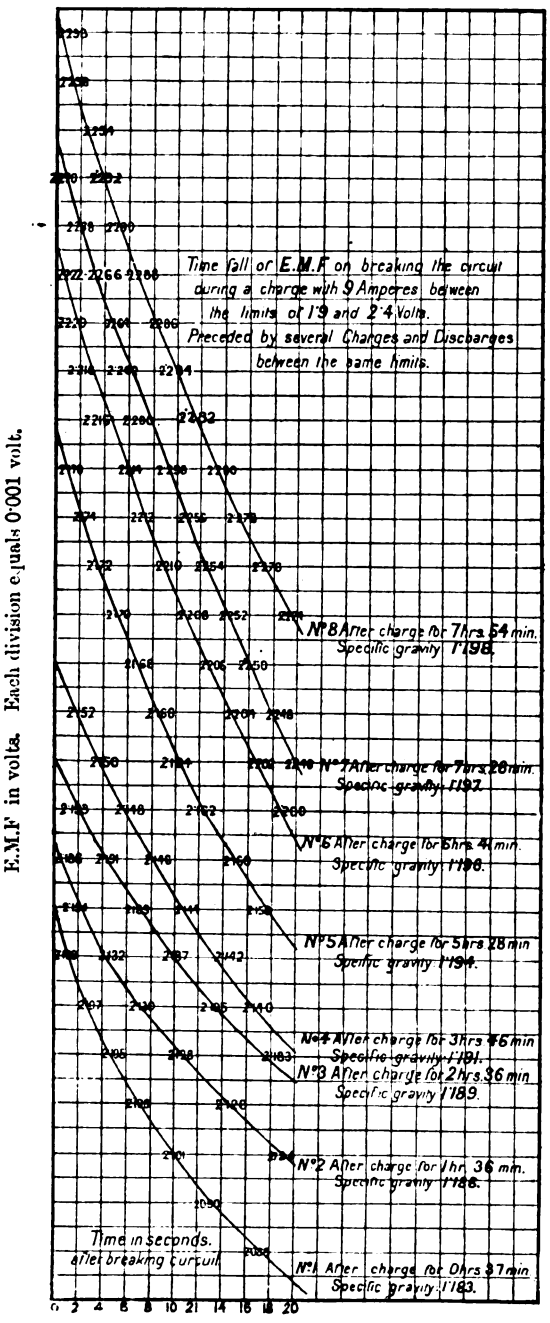
We give in Fig. 11 an example of the time fall of the E.M.F. on breaking the circuit for eight periods of 20 seconds during the charge. The curves are all drawn to the same scale, but, in order to get the curves into a reasonable space, a different zero line has been employed in drawing each curve. The actual E.M.F. in volts per cell is given for several points on each curve, so that the time rise at any period of the charge can be easily seen. The E.M.F. at the moment of breaking the circuit in each case is, as already explained, obtained by seeing at what point the curve cuts the vertical line through the time 0. The value of this point in volts is, in fact, what an infinitely dead-beat voltmeter would indicate immediately after the circuit was broken. It will be observed that the time fall of E.M.F. on breaking the circuit becomes more and more rapid as the charge continues.

Digitized by Google

The top curve in Fig. 12 gives the potential difference at the terminals of one accumulator, charging with nine amperes; while the second curve gives the simultaneous values of the E.M.F., being, in fact, the curve drawn through points whose abscissæ are the times—0 hr. 37 min., 1 hr. 36 min., &c.—for which the eight curves on Fig. 11 are drawn, and whose ordinates are the values of the points where these curves cut the vertical line drawn through the zero of time in Fig. 11, or time when the charging circuit was broken. The lowest curve on Fig. 12 gives the resistance of the cell at any moment during the entire charge with nine amperes, the ordinates of this curve being calculated from the formula

$$\frac{V - E}{9}$$

when V and E are values of the potential difference and the E.M.F. of the cell at the same instant.



E.M.F in volts. Each division equals 0·001 volt.
Time fall of E.M.F on breaking the circuit during a charge with 9 Amperes between the limits of 1·9 and 2·4 Volts. Preceded by several Charges and Discharges between the same limits.
N°8 After charge for 7hrs 54 min. Specific gravity 1·198.
N°7 After charge for 7hrs 26 min. Specific gravity 1·197.
N°6 After charge for 6hrs 41 min. Specific gravity 1·196.
N°5 After charge for 5hrs 28 min. Specific gravity 1·194.
N°4 After charge for 3hrs 46 min. Specific gravity 1·191.
N°3 After charge for 2hrs 36 min. Specific gravity 1·189.
N°2 After charge for 1hr 36 min. Specific gravity 1·186.
N°1 After charge for 0hrs 37 min. Specific gravity 1·183.
Time in seconds after breaking circuit.

FIG. 11.

positive plates, each surface of which is $9\frac{1}{4}$ into $9\frac{1}{4}$ inches, and that all four surfaces are equally active, it follows that the mean resistance of the 1888 E.P.S. type of cell while charging with the maximum current density allowed—viz., 3·787 amperes per square foot—is about 0·11 ohm per square foot of positive plate.

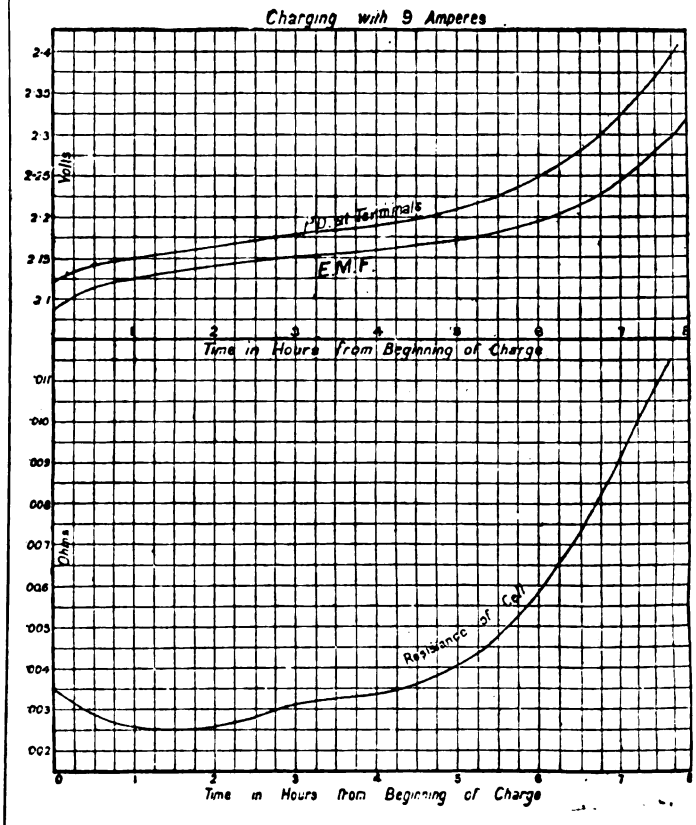


FIG. 12

Fig. 13 gives the potential difference at the terminals of one of the cells during the whole of a discharge with 10 amperes, the simultaneous values of the E.M.F. and of the resistance. The resistance at the commencement of the discharge is a little higher than at the commencement of the charge, and the minimum

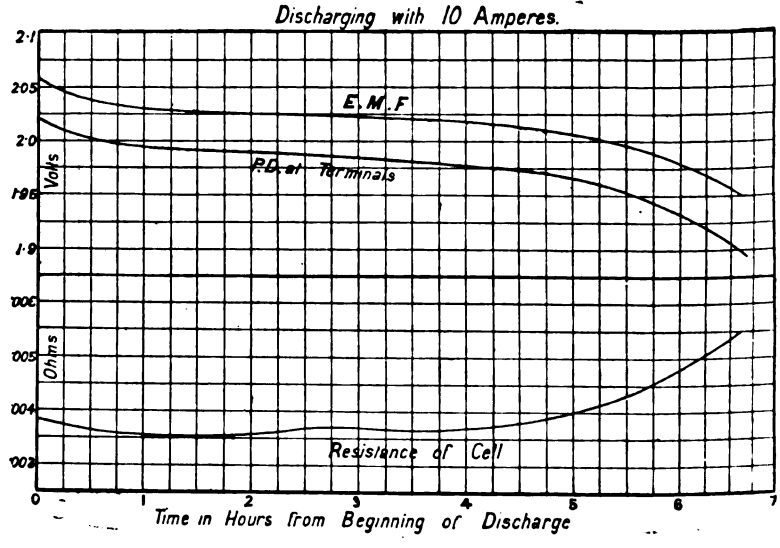

FIG. 13.

As the charging proceeds the resistance of the accumulator at first falls, and reaches a minimum; it then increases, at first slowly, but as the charging approaches the finish the resistance rises very rapidly, so that when the potential difference per cell is 2·4 volts the resistance is five times as great as its minimum value, which is reached shortly after the commencement of the charging. Taking 0·045 ohm as the average resistance during charging, and remembering that there are in these cells two

value to which it diminishes is not as low as the mimimum attained by the resistance in charging. At the end of the fifth hour of discharge and charge the resistance is practically the same. After tha, however, there is a marked difference: the resistance in dischar ing does not rise as rapidly as in charging; and hence, since, in addition the time of a discharge is necessarily less than of a charge, the resistance never reaches as high a value in discharging as in charging.

Digitized by Google

If we take 0·038 ohm as the mean resistance during a discharge with 10 amperes, then it follows that the mean resistance of the 1888 E.P.S. type of cell while discharging with the maximum current-density allowed—viz., 4·208 amperes per square foot—is about 0·09 ohm per square foot of positive plate.

Both in charging and in discharging with constant currents, the greater part of the time variation of the potential difference at the terminals of an accumulator is due to an actual variation in the E.M.F. itself; and it is only towards the end of the charge and of the discharge, when the resistance of the cell becomes relatively large, that the slope of the potential difference curve becomes practically different from that of the E.M.F. curve.

We may mention, in conclusion, that the results which we have obtained with accumulators made to go for long periods through definite cycles in charging and discharging, have been so interesting that we are now engaged on the design of an apparatus which will automatically keep the current constant for any time at any pre-arranged value, which will automatically change over from charge to discharge, or from discharge to charge, when the potential difference per cell reaches any pre-arranged limit, and which will record the potential difference at the terminals of the cell, and also its E.M.F. during the whole period.

We hope, therefore, at some future period to be able to present a graphical record of the life-history of accumulators from their first formation to their death.

[The discussion which followed the reading of this paper will be given in our next issue.]

LONDON CHAMBER OF COMMERCE.

Meeting of the Electrical Trades' Section Committee.

A meeting of the Electrical Trades Section of the London Chamber of Commerce was held on Wednesday last at the offices, Botolph House, Eastcheap; Mr. R. E. Crompton in the chair.

The ASSISTANT SECRETARY (Mr. Musgrave) stated that full reports of the last meeting had been given in the technical journals, and these as well as the minutes were taken as read.

Mr. MUSGRAVE then read the following letter which had been received from the Board of Trade:—

"*Electric Lighting Act*, 1888.

"Board of Trade (Railway Department),
"London, S.W., July 16, 1890.

"SIR,—I am directed by the Board of Trade to acknowledge the receipt of your letter of the 23rd ultimo, enclosing a copy of a resolution passed at a recent meeting of the Electrical and Allied Trades Section of the London Chamber of Commerce, on the subject of the regulations to be issued by this Department, under Section 4 of the above-mentioned Act, with respect to overhead wires, and to state that the Board of Trade have carefully considered the resolution adopted by your Chamber, and the arguments in support of it contained in your letter.

"In the preparation of the regulations in question the Board of Trade consulted the Council of the Institution of Electrical Engineers, whose members possess the highest scientific attainments, and have also large practical acquaintance with the working of electric light undertakings.

"The Council devoted a great deal of time and care to the consideration of the subject, and the regulations as now drafted were adopted, with some modifications not affecting the questions raised by your Chamber, on their recommendation.

"The Board of Trade, while anxious to avoid any undue interference with trade, are compelled to have regard to the safety of the public; and they desire me to say that they regret to be unable to modify the model Regulations, as desired by your Chamber.

"I am, however, to add that they will consider carefully, in the case of any particular installation on the series, or other similar system, any application for a modification of Regulation 12, which is supported by the Local Authority of the District.

"I am, Sir,
"Your obedient servant,
"HENRY G. CALCRAFT.

"The Secretary London Chamber of Commerce."

The CHAIRMAN said that probably nothing could be done till November, when it would be possible to re-summon the Committee of the Institution of Electrical Engineers who were alluded to in the letter, and on whom the responsibility was cast. He held that they should not cease to agitate until the rules were made practicable. The use of overhead wires in accordance with these regulations was almost impossible. Major Cardew had stated that reasonable requests for modifications would be considered; but three applications had been made to the Board of Trade, and they had all received a point-blank refusal to consider any suggested modifications. Besides the fact that the conductors made in accordance with the regulations were of ridiculous dimensions, the cost was increased from £28 to £78 per mile. He proposed that that Section of the Chamber should address the Council of the Institution on the subject.

Mr. SWINBURNE pointed out that there were several other equally impracticable rules which had been made by the Board of Trade, such as enclosing transformers in metal cases, and the use of iron tubes for leading-in wires, which were to be of a thickness of a quarter of an inch; this was thicker than gas pipe, and therefore special pipe would have to be used.

It having been pointed out that the rules alluded to by the last speaker had not yet been issued, and that instead of taking particular cases it would be better to urge the inadvisability of framing regulations for a new industry, when even experienced engineers could not foresee the results of proposed rules, which should not be hard and fast,

Major FLOOD PAGE suggested that the Chairman should be requested to draw up a statement of the difficulties which have arisen in consequence of the new regulations, and that the Institution of Electrical Engineers be asked to meet a committee of the Section to discuss the question, since the united action of the two bodies had proved to be satisfactory as to the need for establishing a standardising laboratory.

A resolution was passed to this effect.

The first matter on the agenda was the resignation of the Technical Correspondent. A letter containing the resignation was read, and a vote of thanks was passed to Mr. Trotter, who expressed his regret at being unable to continue to fulfil the duties of the post.

Mr. MUSGRAVE read a communication from the Chemical Trades Section, calling attention to certain evils arising from the improper use of disclaimers in patent law, and asking for the co-operation of those Sections of the Chamber which are interested in inventions.

Mr. SWINBURNE, who had already studied the circular issued by the Chemical Section, gave a very complete account of the difficulty. It arose, he said, from the fact that in the old days of the former patent law, only one specification was required, and it was, therefore, fair that the inventor should be allowed to amend by disclaimer; but the present system of provisional and final specifications did away altogether with the need for disclaimers. He contended that there was no need to amend the system of disclaimers; but now that we have provisional specifications, the need for disclaimers is gone. In no other countries where there are provisional specifications are disclaimers allowed. In the United States, where there is no provisional specification, it is the common practice to draw up the claims of a patent with the view of amending them by disclaimers. The inventor can then wait until after he has made his experiments, and he then disclaims all the methods which he finds to be unsatisfactory. In the United States, a patent for a combination of five separate things is protected by a patent which gives all the possible combinations; first, one of the things in combination with the other four in turn, then combinations in sets of four with the other things, then in sets of three, and so on. The patentee can at a later date wipe out any of these. A patent is a contract between the public and an individual. It was in the first case a monopoly given to anyone who introduced a new process from abroad, then it was extended to cover inventions. It is manifestly unfair that one party to the contract—the public—cannot alter it in any way, while the other—the inventor—is allowed to alter and amend the contract when he wishes. This would never be permitted in any other form of contract.

Mr. MUSGRAVE said that the circular also referred to patents which were taken out and which were not worked.

Mr. SWINBURNE referred to the work of the recent International Convention, and pointed out the different ways in which this affected foreigners. The Austrian patent law demanded that the patent should be worked at least once a year, to maintain its validity. This had given great inconvenience to an engineer who had invented a new way of blowing up iron-clads.

Major FLOOD PAGE said the trade had been very much hampered abroad by the necessity for working foreign patents, and it was impossible to get a definite opinion from the most skilled foreign lawyers as to what constitutes the working of a patent.

Mr. W. W. BEAUMONT said that the matter was a very important one, and thought that the question should be discussed as to whether the system of provisional specifications should be continued, or whether, as an alternative, amendments should be allowed for one year.

After a further discussion, it was decided to co-operate in the matter with the Chemical Trades Section.

Mr. MUSGRAVE stated that the date for receiving applications for space at the Frankfort Exhibition had been extended to September 30th.

A letter was read from the manager of the Edinburgh Exhibition, asking that jurors might be appointed, as suggested by the Section.

Major FLOOD PAGE reminded the meeting that the principal suggestion which the Section had made was to the effect that there should be no awards.

Mr. ALEXANDER SIEMENS said that a similar application had been made to the Institution of Electrical Engineers, and that as no Council meetings are being held, Mr. Webb had called on him to ask what should be done. He thought that it was obvious that members could not be called together at this time of the year, when nearly every one had made his holiday arrangements, and few would care to alter them for the sake of going to Edinburgh at his own expense for this purpose. Mr. Webb had written to ask what the duties were, and had been informed that the jurors would be expected to assist in carrying out experiments to verify statements as to efficiency and output of dynamos, &c. Mr. Webb had written to say that, as far as he could ascertain, it was out of the question that the Council would nominate any of its members for this purpose.

Major FLOOD PAGE remarked that the question should have been raised when the Institution was holding meetings and Council meetings in Edinburgh, when the matter might easily have been arranged.

Mr. ALEXANDER SIEMENS added that Mr. Forrest had received a similar application, and had replied that the Institution of Civil Engineers would be unable to act in the matter.

Digitized by Google

After further discussion, it was agreed that a letter should be written explaining why the Section would be unable to give any assistance.

Mr. TROTTER reported that the draft classification of merchandise traffic, under the Railway and Canal Traffic Act of 1888, had been issued by the Board of Trade; and submitted the following analysis, showing the basis and the result of the enquiry which was held before the Board of Trade, so far as the electrical trades are concerned:—

—	Old classification.	Clearing House.	Class in Deposited Schedule.	Class proposed by Chamber of Commerce	Class recommended by Board of Trade.
Dynamos in cases ...	2	3y	Omitted	2	2
Batteries, packed ...	3	3	3	2	3
Sulphuric acid	4	Special	Omitted	C	not dealt with
Telegraph batteries..	3	3	Omitted	3	3
Electric storage batteries	2	2	3	2	2
Cables	4y	4y	4	3	3
Carboys, not glass, empty, not returned..... ...	4	4	Omitted	4	4
Carboys, empty glass	3	4	Omitted	4	5
Cars, tramway	Special	Special	Omitted	Special	carriage class
Castings, iron, malleable	1	1	2	1	1
Castings, iron, steel, light	1	1	2	1	2
Castings, steel	3y	1	3	1	3
Telegraph insulators	1	1	Omitted	1	1
Sheet iron annealed.	1	1	Omitted	1	not packed B
Mouldings	3y	3y	Omitted	2	3
Telegraph posts	1	1	Omitted	1	B
Reflectors, glass.....	4	4	5	4	4
Sponge cloth	2	2	Omitted	2	3
Steel bars, bundles...	2	2	Omitted	2	2
Telegraph cable	4y	4y	Omitted	3	3
Wire, cotton covered	2	2	4	2	2

He observed that the results were on the whole very satisfactory; but he drew the attention of the Chamber to the discrepancy between the concessions of the Companies and the draft classification in the matters of "sheet iron" and "telegraph posts," which are only provided for in 4-ton lots.

The meeting then terminated.

THE HASTINGS AND ST. LEONARD'S ELECTRIC LIGHT COMPANY.

Mr. E. T. Mercer, managing electrician and engineer of the Hastings and St. Leonard's electric supply station, sends us the following particulars of the engines and boilers used by him, together with details of their performance. The underground mains of this Company were described in *The Electrician*, Vol. XXIV., page 186.

The plant is started about half an hour before sunset, and the incandescent lamps are switched off at 12 p.m. About 800 of these are run by contract, this being the total number at this time of the year, most of the shops being closed before light is required. These 800 lamps are contracted to run to midnight. The lamps, of 8 candle-power, 30 volts, are supplied by Edison, Swan, and Co., Ponder's End. The arc lamps are also started at the same time, but are extinguished at 11·15 p.m., and are also supplied by contract. The 38 arc lamps are of the Brush type, known as of 2,000 candle-power nominal, the whole are driven from four Brush No. 8 machines, with separate circuits. The average pressure is about 5,000 volts, the current 10 amperes for arc lamps in one circuit, and 9 amperes for incandescent in three circuits.

The driving power consists of two 40 horse-power nominal engines, and boilers, known as undertype, high-pressure cylinders, 14in. diameter and 22in. stroke, and made by Messrs. Robey and Co., Globe Works, Lincoln. Also one double flue Lancashire boiler, made by Messrs. Duncan, Stewart and Co., London Road Iron Works, Glasgow. The three boilers are connected into one main steam pipe, with a working pressure of 95lbs. per square inch.

The boiler flues are run into a chimney 75ft. high and 3ft. square at the base inside measurements, with natural draught. The fuel burned is gas coke and small coal. About one of small coal to three of coke is used, and this is found to make a first-class fire for generating steam. There is no difficulty in maintaining a constant pressure of steam.

Two boilers are working. The engines are both driving on one intermediate shaft, and running at 80 revolutions per minute. The fires are lighted now at 6 p.m., and the lights are turned on at 7.30, making a run of 4½ hours. Twenty-four cwt. of coke and small coal is burned. The engines are developing 65 indicated horse-power, or 130 indicated horse-power together, for 4½ hours, making a total of 585 indicated horse-power hours, during which time 2,300 gallons of water are evaporated. (The horse-power given above was taken from a diagram each hour with a Richards indicator). This gives 4·6lbs. of coke and small coal per indicated horse-power per hour, and 8·6lbs. of water evaporated per 1lb. of coke and small coal. The price of coke and small coal is 9d. per cwt., so that for 18s. 2,300 gallons of water are evaporated, and produce 585 indicated horse-power hours, to maintain 800 incandescent lamps and 38 arc lamps for one night of 4·5 hours.

The cables are those supplied by the Silvertown Gutta Percha and Telegraph Works Company, and give perfect satisfaction after several years' use.

THE SCHISEOPHONE.

This instrument, as its name so clearly suggests, is intended to act as a "flaw sounder." It is a modification of Prof. Hughes' induction balance, and has been invented by Captain De Place.

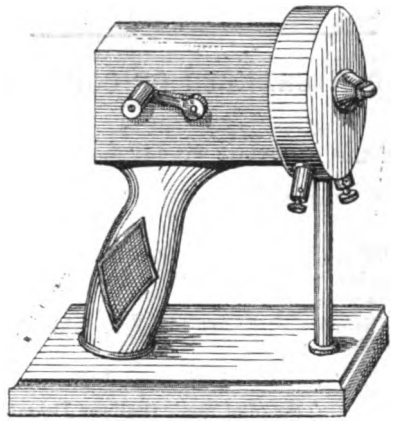

Fig. 1.

Fig. 1 represents an induction coil having a reciprocating core, which can be set in motion by means of a crank, the whole being mounted on a stand with a handle.

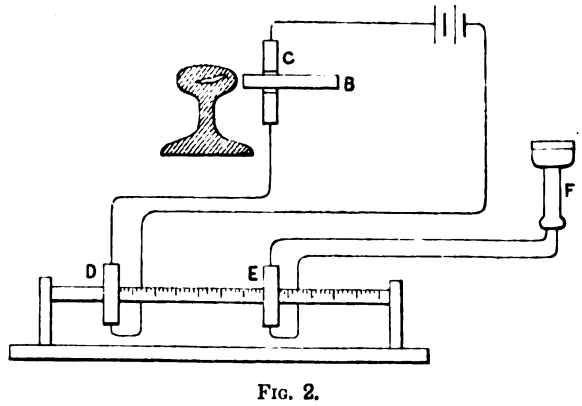

Fig. 2.

Fig. 2 is a diagram of the arrangement. B is the core which moves longitudinally in the coil C. The core is made to strike the object to be tested. A continuous current is sent through the coil C and a coil D, the latter being fixed at one end of an induction balance. A similar coil, E, sliding on a graduated rod, is connected with a telephone. When the core B strikes a sound portion of the metal, a certain quality of click will be heard in the telephone. This noise may be reduced to a minimum, or may be extinguished by adjusting the coil E. When the core B strikes the object to be tested in the neighbourhood of a flaw, the sound in the telephone is increased. The instrument is said by *La Nature* to have given very satisfactory indications of flaws in rails at the depôt of the Chemin de Fer du Nord; in every instance the rail when broken showed a flaw at the place indicated. We think

Digitized by Google

that the sensitive state of coil E ought to be produced not merely by its distance from D, but by its relative position between D and another coil. A delicate balance at which the click might be extinguished could then be attained, and an alteration either of decrease or increase of the current in coil D would give a sound in the telephone. We should imagine that though the instrument may be useful in testing a long homogeneous bar, a change will take place near the ends, and it could not be used for testing an object of irregular shape.

TRANSMISSION OF POWER AT DOMENE (ISERE).

A satisfactory example of the transmission of water-power by electricity has lately been started near Grenoble. The water is dammed, with an effective head of 230ft., and is conducted by a sheet steel pipe to the turbine. The generating dynamo is coupled directly to the horizontal shaft of the turbine, and is connected to the two cables of an aerial line, through which the power is transmitted to the motor at Montier, a distance of a little more than three miles. The general conditions of working the plant are, according to *Le Génie Civil*, as follows:—

Generator...	300 h.-p., 240 revs. per min.
Motor	200 ,, 300 ,, ,,
Pressure	2,850 volts.
Current	70 amperes.
Resistance of line.....	3·474 ohms.
,, dynamo fields	0·950 ,,
,, ,, armatures	0·984 ,,
,, motor fields..	0·731.
,, ,, armatures	0·690.
,, total of circuit	6·829.
Electrical efficiency ...	83 per cent.
Mechanical.....	65 ,,

Since this plant was started in the November of 1889, it has not ceased to work day or night, and although the care of the machines presents no difficulty, no increase whatever of the staff has been required. Four men are employed, two at the generator, and two at the motor, each being in attendance for twelve hours. A telephone line is run on the same poles as the working line. Shortly after it was started a frost set in, entirely stopping the traffic, and since that time until March 15th the communication by the roads was cut off. The line was struck several times by lightning, but both generator and motor were fully protected. The power is used for driving a paper mill, and the economy is found to be very marked as compared with the cost of fuel.

ELECTRIC LIGHTING IN ST. PANCRAS.

A special meeting of the St. Pancras Vestry was held on Wednesday evening at the Vestry Hall, Camden Town, under the presidency of Mr. Churchwarden Nathan Robinson, L.C.C., to consider the report of the Electricity Committee, recommending the acceptance of tenders amounting in the aggregate to £50,946. 4s. 3d. for the provision of plant and execution of works necessary to supply the parish with electricity for the purposes of light and motive power of an extent sufficient for 10,000 incandescent lights of 16 candle-power and 40 arc lights.

Mr. ANDREW SWEET, the Chairman of the Committee, who had moved the adoption of the report, said the Vestry by its Provisional Order was empowered to charge 7d. or 8d. per unit. It was allowed to make 7 per cent. profit, and when this was reached the consumers were entitled to a reduction of the cost of the light. In one of the committee's reports it was suggested that the electric light could be supplied at 4½d. per unit. The London County Council had already lent the Vestry £10,000 to acquire the site in Stanhope-street for the purposes of an electric station.

Mr. CLEMENTS said they had no estimate in the latest report of what the profit would possibly be. Including the cost of repaying principal and paying interest on the loan to be secured—the loan being for 30 and not 42 years—and allowing £5,000 for extras, he estimated that the Vestry, if they adopted the report, would commit itself to an expenditure of £71,000. He doubted whether the County Council would be able to advance the Vestry a loan of £50,000 for the purposes of electric lighting.

Mr. CROW proposed, as an amendment, "That the report of the committee be referred back to the committee to prepare and present to the Vestry an estimate of the expected profits, based upon the altered figures of cost now found necessary, and that the further consideration of the report be adjourned until that estimate has been presented." He contended that a private company could supply the electric light better than a public body, and that private individuals could do so better than either.

Mr. VEARS seconded the proposition.

Upon a division after discussion, the amendment was negatived by 47 to 7, and, in the result, the original motion for the adoption of the committee's report was carried, and the necessary tenders were accepted.

The various competing tenders were as follows. It will be seen that the figures differ slightly from those given in our last issue:—

Contract No. 1.—Buildings.

Holliday and Greenwood, Loughborough Works, Brixton	£5,532	0	0
Mowlem and Co., Westminster	5,237	0	0
Pattinson, 5, Whitehall, S.W., and Rushington, Sleaford	5,130	0	0
Kirk and Randall, Woolwich (accepted)	4,629	0	0

Contract No. 2.—Boilers.

Fraser, Cannon-street, E.C...	£4,592	0	0
Crompton and Co., Chelmsford	4,049	0	0
Electrical Engineering Corporation	3,835	0	0
Taunton, Delmard, Lane and Co., Birmingham ...	3,772	0	0
Babcock and Wilcox Company, Newgate-street, E.C. (accepted)	3,674	10	6
Sharp and Kent	3,674	0	0

Contract No. 3.—Engines, Dynamos, &c.

Siemens Bros. and Co. (Tender No. 2)	£27,349	0	0
Brush Electrical Engineering Co.	20,078	0	0
Siemens Bros. and Co. (Tender No. 1)	20,004	0	0

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 25, 1890.

Prof. Elihu Thomson's New Motor.—Professor Elihu Thomson has just patented a form of dynamo that is almost as remarkable in its way as the Duncan motor. It is peculiar in that there is no external field, and hysteresis is reduced to a very low figure. The field coils are only two in number and embrace a massive cylinder, having around its centre a star-shaped mass that constitutes a group of six consequent poles. The magnetising coils are wound on iron bobbins that support the bearings on which the internal cylinder revolves. The whole cylinder of iron connects the base-plates of these bobbins and shuts in the whole machine. Within the central portion of the cylinder is a belt of poles pointing regularly inwards and just clearing the revolving poles. Around these outer poles are wound the coils of the armature, which is, of course, stationary. The revolving poles are all of one polarity and the stationary ones all of the other, so that when the former are set in motion a rapidly alternating current is induced in the armature. It will be seen that there are no sliding contacts of any sort in this machine, while the hysteresis is necessarily small.

Lighting of New York Streets.—The difficulty between the Gas Commission and the electric light companies still continues.

Digitized by Google

The bids last May for street lighting were practically at the old rates until January 1st, when a newer and higher rate will come into effect. The Gas Commission has accepted the bids up to January 1st, thus leaving the question of an increased price later still open. Mayor Grant protested through the proceedings as usual, and put himself on record as in favour of lighting with gas rather than coming to any sort of terms with the electric companies. One of the latter declares in the most outspoken manner that, at the old prices, there was no profit in city lighting, and challenges inspection of its books in proof of this assertion.

Westinghouse Traction Work.—The Westinghouse Electric Railway Company is pushing vigorously, and has already taken a number of contracts for the equipment of electric roads. A few of their new cars have recently been in operation in Pittsburgh, Pa., and have given excellent satisfaction. The new Westinghouse system is very closely similar to the Sprague and Thomson-Houston systems now in such extensive use, although differing in some mechanical details. The machinery is said to be very well made and to promise high efficiency, but there is nothing specially novel about it. The Westinghouse Company is also preparing to put on the market a new alternating motor, the details of which have not as yet been made public.

Another Motor for Alternating Currents. — Still another alternating motor is about to make an appearance, invented by Mr. Slattery, electrician of the Fort Wayne Electric Company. The new machine is said to be self-starting, even under full load, and to have a large output in proportion to its weight.

The Consolidation.—Nothing has come, so far, of the much-talked-of plan of consolidating the Thomson-Houston and Edison Companies. There is some hitch in the arrangement, but any form of arrangement between the parties immediately concerned seems to be deferred. Both companies are doing a very large amount of business, the Edison Company in its new and efficient organisation having made specially rapid progress of late.

The Fire at the Western Union Telegraph Office.—The fire in the Western Union building recently proved to have caused far smaller damage than was at first probable. The actual injury done will probably be repaired for less than a quarter of a million dollars. The company displayed great activity in carrying out repairs, and is now able to handle nearly its normal volume of business, although its forces are still somewhat scattered. Large additions are contemplated to the building when it is reconstructed, and more care will probably be taken in rendering it fireproof and in insulating and distributing the wires so as to prevent the possibility of a similar accident again.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *Aug.* 5, 1890.

The lighting of the boulevards and quays of the Canal St. Marstin by arc lamps is daily increasing. Paris will soon be surrounded by a circle of lighting. There have been some experiments in lighting the streets by glow lamps; amongst others the Rue des Halles by Khotinsky lamps, in groups of two or five in the gas lanterns, the current being supplied by the municipal station at the Halles. The Rue Auber has also been lighted by Edison-Swan lamps, singly or in threes, in the gas lanterns, with small white reflectors. Where 16 candle-power lamps are used, the light is much better than that of gas. These lamps are run from the station at La Place Clichy. On the Boulevard Montmartre, near the corner of the Faubourg Montmartre, the large café "La Splendide Taverne," is lit with 550 16-candle lamps, 8 Pilsen arcs of 10 amperes, and 2 arcs of 8 amperes. The compound engine by Dufaut and Robatel, of Lyons, is placed in the cellars; it runs at 78 revolutions per minute, and drives a Fabius Hanrion dynamo for 350 amperes at 110 volts, at 550 revolutions per minute. Collet boilers supply steam at 114lb. per square inch.

The Popp Company is about to change the whole system of distribution which it established last year; this system consisted of cast pipes, with joints made with india-rubber. The system which they are now adopting consists of a cast-iron box of rectangular section in which they place five double casings, resting on paraffined wood. The box is closed with a cast-iron lid. Before each house a branch box is established. The connections between the cables of the customers and the mains, are made with screw couplings, without soldering. In the high-pressure service for charging the accumulators, the cables are coloured red, while those for distribution at low-pressure are black.

AUSTRALIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

SYDNEY, *June* 29, 1890.

ELECTRIC TRAMWAYS.—The work in connection with the trial of an electric tramway on the Thomson-Houston system is progressing rapidly, and it is expected that in about two months from date the first cars will be running. The experiment is causing considerable interest in Sydney, a change from the present steam system being considered desirable. Should this experiment be as successful as the promoters anticipate, and should it meet with the approval of the local authorities, there is little doubt that a large business will be the ultimate result. Another electric tramway project is being pushed by the Crompton Electric Company, this time on the accumulator principle. The scheme is, however, at present only in its first stage, and some time must necessarily pass before its completion.

LIGHTING OF TRAINS.—The New South Wales Railway Commissioners have been taking steps to improve the lighting of the trains on their lines, and to this end they have just completed a most successful experiment with the electric light. The system adopted was the accumulator system. The train on which the experiment was made was the express to Albury, and a sufficient charge was stored to last for the return trip. The whole affair appears to have been a success, and it is expected that the Commissioners will now take steps to introduce the new illuminant into more of their trains. The accumulators used were those of the Crompton Electric Company, while the lamps were the Thomson-Houston.

GROSS'S ELECTRIC COMPASS.—This invention, of which Mr. Gross is the inventor, was put to a thoroughly practical test last week on board the s.s. "Bulimba," the compass of which vessel was replaced by one of the new design. The object of this invention is to indicate by an electric bell placed in the captain's cabin any deviation from the course laid down, through the carelessness or neglect of the man at the wheel. From a conversation held with those on board the "Bulimba" it would certainly appear to have had a good effect on the sailors, the steering having been very much better than usual on this trip. Those connected with the invention appear to have confidence in the success of their enterprise, and if, as it would seem, it is going to lessen the dangers to life and property at sea, it is to be hoped that shipowners will take it up.

CORRESPONDENCE.

PROVING OHM'S LAW.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is not quite clear from Prof. Oliver Lodge's letter (p. 359) in what way he wishes Ohm's law to be taught—or proved. He first says that it is, when stating Ohm's law in the usual symbolic way, ridiculous to begin by defining resistance as a ratio. And then he goes on to state Ohm's law as a ratio, and calls that ratio "resistance." Where is the difference? To be sure, he qualifies it by saying that such ratio, called resistance, is not a function of the current intensity; but that brings us no "forrader," because he has already cut away the need for such qualification by adding previously the proviso that the conductor must be "in a given state." If it is "in a given state," then either the current intensity through it has an effect on its state, or else it has not. If the current intensity has no effect on its state then the proviso about resistance not being a function of current intensity is superfluous. If, on the other hand, the current intensity has an effect (as we know it has, in fact, in iron and in bismuth) on its state, then it is an absurdity to say that the resistance of the conductor *in a given state* is not a function of current intensity. Will Professor Lodge kindly reconsider the phraseology of p. 359, which, partly by no fault of his, is "in a given state" of admirable derangement, a function of other variables than his own usually lucid current of ideas?—Yours, &c.,

SILVANUS P. THOMPSON.

[We regret that the proof of Dr. Lodge's letter, which was posted on Tuesday, 26th, was not delivered to him until

Digitized by Google

Friday morning, and allowed him no opportunity of making a correction. For "rates" read "ratio." The author meant, "Ohm's law is obeyed when simple proportionality holds between current and E.M.F. in a given conductor."—ED. *E.*]

EDISON AND SWAN UNITED COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest your criticism on the Edison and Swan Company's accounts for the year ended 30th June last, but I am sorry to see you have not touched upon what I consider to be the only unsatisfactory feature about them, and one which I think will be found very difficult to explain. It is this—the cost of producing the lamps sold for £118,865 was £73,719, as against £62,529 for making £111,715 worth in the previous year. We have thus an increase in the sales of £7,150, and of expenses in manufacturing the articles sold £11,190. At first I thought this could be accounted for by the very large increase in the stock, but when at the meeting Mr. Forbes explained that this particular increase was almost entirely due to the purchase of a large quantity of platinum, I cast about for some other explanation, and, so far, I have been unable to find it. There has certainly been no reduction in the net selling price of the lamp; in fact, I fancy, if anything there has been a slight increase.

Now, if lamps, and good lamps, too, can be made and sold on the Continent at 1s. 3d. each, how is it that the same thing here costs somewhere about 2s. to be manufactured, without reckoning one farthing for general expenses (*i.e.*, Directors' fees, rent, &c.) or depreciation of plant? Even in America where labour is so dear, incandescent lamps are *sold* at about 2s. each, and doubtless at a profit:

How you arrive at the amount of the Directors' and Auditors' fees paid by the Edison and Swan Company is a puzzle to me. Perhaps you will not mind letting me know what these figures are, and, at the same time, be good enough to tell me how you calculate the proportion of net to gross profit, which you say is 51½ per cent.?

Finally, I make the amount carried to reserve (£8,093) equal to more than 13 per cent. of the profit of the net balance in the profit and loss account.—Yours, &c., A SHAREHOLDER.

August 2, 1890.

[We are obliged to our correspondent for pointing out a slip, by which we gave the Directors' fees of Crompton and Co. as those of the Edison and Swan United This does not affect our point, viz., that they are not excessive. The balance, £61,115, was taken as the net profit, and compared with £118,865. The reserve fund was that on the balance-sheet, not on the proposed appropriation of profits. We do not care to follow our correspondent in his criticisms, as it is not our custom to enter into financial controversies nor (except in serious cases) to dwell on "unsatisfactory features." Our object was rather congratulation on the details.—ED. *E.*]

THE PRICE OF ELECTRICITY AT BATH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I, together, no doubt, with many of your readers, was amazed to hear that at Bath Mr. Massingham proposed to charge 6s. only per 10 candle-power lamp for current supplied; but, considering that Mr. Massingham had had some experience of central station lighting, I withheld from expressing an opinion in the matter until some explanation was forthcoming, or some of your "knowing" correspondents had expressed *their* opinion of the venture.

I therefore turned to your issue of to-day with more than usual interest, and although I cannot go so far as to say with your correspondent that 1,800 hours per annum is a fair estimate of the time that lights are used, I can, from personal experience, say that 700 to 800 hours is not too much to calculate when the general lighting of a town is gone in for, including hotels, bars, ordinary shops, underground cafés, &c.

In the case of a Company with which I am connected, and where we have about 6,000 10 candle-power lights going, the average hours of lighting is 770 hours per annum, which would mean about 2¾d. per unit if charged at Mr. Massingham's rate.

I venture to say therefore that the price of 6s. per annum is a ruinous one, but if the Bath installation can be made to pay, or to pay itself, at this price, then the electric lighting star will indeed be in the ascendant and the career of gas companies for illuminating purposes will be short, especially in the south, for the Bath rate of charge must be equal to very little more than 2s. per 1,000 feet for gas.

While, therefore, doubting the success of the scheme, I wish it every success, and shall watch its progress with interest. I enclose my card, and remain, yours, &c.,

August 1, 1890. NORTHERN.

TRADE NOTES AND NOTICES.

SOFIA.—The Agent and Consul-General states that any British firms desirous of tendering for the lighting of this town by electricity should lose no time in communicating with M. D. A. Zenow, of Sofia, or with the Mayor, M. D. Pethoff.

DISSOLUTIONS OF PARTNERSHIP.—The following firms have dissolved partnership:—George Weston and William Prince, electricians, Dashwood House, New Broad-street, London, E.C.; and Louis John Crossley, Walter Emmott, and John Frederick Harrison, electricians, Bradford.

TENDERS WANTED.—The Helston Town Council invite tenders for lighting the public streets and buildings in Helston by gas, oil, or electric light. Full particulars may be obtained from Mr. J. G. Plomer, Town Clerk, to whom tenders are to be sent by the 16th inst.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

COMPANIES' MEETINGS & REPORTS.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors in the Anglo-American Telegraph Company (Limited) was held at Winchester House, 50, Old Broad-street, on the 1st inst., under the presidency of the Marquis of Tweeddale.

The SECRETARY (Mr. T. H. Wells) read the notice calling the meeting and the minutes of the last meeting.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: I have to apologise for the absence of our respected Chairman, who, I regret to say, is suffering from severe indisposition, and is, therefore, unable to attend to-day. You will have noticed from the report that the traffic receipts show an increase of £2,025 over those of the corresponding period of last year. This increase is satisfactory, first, because the half-year under review is the less profitable of the two, and, in the second place, because it is mainly due to the establishment of three new offices in the City of New York. This has brought us more in contact with the telegraphing public of that important city, and the benefit of these offices will no doubt be still further realised when they are better known than they are at present. There is one very satisfactory feature in our report, and that is that the whole of our cables are in good condition. We have had fewer faults to repair than usual, in a great measure owing to the alteration made in the position of the Duxbury cable, which was referred to on two previous occasions, and which has realised our expectations. But not only are our own cables in good working order, but all the cables in the "pool" are in equally good condition. We have learned that one of the cables of the Western Union Company, which has been out of order for some time, has been repaired at a depth of something like 2,500 fathoms. Our traffic has been conducted during the past half-year with the usual accuracy and efficiency, and, I am glad to add, at a speed higher, I believe, than that of any other company doing business in the Atlantic. I am sorry I cannot report the settlement of the dispute with the Paris and New York Company. We have been expecting to hear of it, I may say, for the past six months; but I have no information that I can give you as to when the decision may be anticipated. Turning to the revenue account, you will observe that the working expenses, when compared with the corresponding period of last year, show an increase of £5,692. This is almost entirely made up of one item, namely, £4,352, which was spent on the establishment and working of the three offices in New York, to which I have referred. The balance is made up of a number of small items, calling for no particular comment. There is another item in the accounts which, I think, demands explanation, and that is repairs of cables which show an excess in expenditure of £2,023. This is really a satisfactory feature, inasmuch as the repairs have been entirely of a character to be charged to revenue. Under the head of renewals the expenditure has been extremely small, being only £552, and consequently nearly the whole of the interest accruing on the investments forming our renewal fund has increased that fund to £968,861, the market value of which is about £50,000 more. The renewal fund, therefore, amounts to rather over a million. You will have noticed, I dare say with satisfaction, that the ship "Minia" earned £4,840. It had been lent to the Direct United States Cable Company to repair their cable. There is only one other item in the report which demands any notice—that is, the acquisition by this Company of the Brest-Salcombe cable. The details are set forth in the report, and I have only to add that the terms on which the acquisition has been made are altogether satisfactory. I do not think I have anything to add to what I have said, but I shall be very happy to answer any questions that may be addressed to the Chair. I now propose:—

"*That the report of the Directors and the accompanying statement of accounts to the 30th June, 1890, submitted to this meeting be, and the same are hereby, received and adopted.*"

Sir JAMES ANDERSON seconded the motion.

Mr. W. GRIFFITH thought that the information given in the report with regard to the acquisition by the Company of the Brest-Salcombe cable was rather scant, and he would be glad to be informed of the amount they were to receive every year out of the joint purse receipts for working and maintaining the cable.

The CHAIRMAN said the information could be easily obtained at the office, and it was a very small matter.

Mr. GARLAND regretted that the whole of the interest had been credited to the renewal fund. He thought there had been scarcely a meeting at which this proceeding had not been objected to by the majority of the shareholders; and he considered that they to ought come to some understanding as to what the amount of the renewal fund was to be. This money could not belong to anybody else but the shareholders, who, he thought, ought to have a voice in the matter; whereas, it seemed to him, they had very little voice respecting it. The Directors had, at the different meetings, said that they would consider it; but it had never been considered sufficiently to use any of it for dividend purposes. He, for one, decidedly objected to the renewal fund being increased to an unlimited amount. There ought to be a stated sum, and if it were trenched upon, it then ought to be increased again to that limit, but it ought not to go beyond.

Mr. GRIFFITH said he thought it was agreed sometime since that the renewal fund should not exceed a million. A committee was formed, and there were considerable discussions on the matter, and this was the tacit understanding which was arrived at between the Board and the Committee. Nominally the fund did not yet exceed a million; but as the value of it was about a million, he thought they were entitled to recall to the Directors the tacit agreement come to in the past. If the value of the

Digitized by Google

securities exceeded a million, he thought the amount had been reached beyond which it was tacitly understood that this fund should not go. They were very willing to accept the report, but he trusted that the Directors would abstain on the next occasion from putting the interest to the renewal fund if the value of the securities was maintained, in which case the interest might be divided among the shareholders. This would be carrying out an implied agreement, and he thought it would make the Board more popular with the shareholders than they were at present.

Mr. HUMPHRIES suggested that the interest on the renewal fund, which had come entirely out of the pockets of the Deferred shareholders, should now be given to that section of the proprietors. It would produce something like 1 per cent. for them, though that would be a very small return for an investment so peculiarly secured as theirs was in this Company. Still, it would be a comfort to those who had hitherto not received anything. He hoped the Deferred shareholders would assent to his proposition that from this time forward the whole of the interest on the renewal fund should be appropriated to the Deferred shareholders, from whose pockets the money now forming the renewal fund had been kept.

Mr. ROBERTS, referring to the first paragraph in the Directors' report, said that the balance was estimated at £152,000, "subject to revision, as the lawsuit between this Company and the Paris and New York Company is still pending." This matter was still pending, and what he wished to know was whether the Paris and New York Company had any claim on this £152,000.

The CHAIRMAN: No. With respect to the renewal fund, let me remind you of the agreement come to in this room some two years ago, by which the Directors agreed that they would stop further contributions from revenue to the renewal fund when that fund amounted to a million, after which the interest of the fund alone would be added to the principal. That was the agreement come to, and I do not think there is any reason to believe that the shareholders, in this room or out of it, would desire so see a change in that respect. It is of the utmost importance in their interests that we should have a very ample fund of that kind; for, let me remind you, our cables are not any younger, but are growing older every day, and we may possibly soon find ourselves obliged to spend a considerable sum on renewals. I am, therefore, afraid that on that head I am not able to hold out any hope of any change being recommended by the Board in dealing with the question of the renewal fund. He then put the resolution in the usual way, and it was carried unanimously.

Mr. GRIFFITH thought that the shareholders ought not to separate without tendering a vote of thanks to the Board of Directors. These gentlemen might not agree with them in all points of policy, but they were showing a friendly spirit towards them, and in the future they might agree with them still more. He thought that the shareholders had to thank the Board for what they had done, and he hoped they would do more for them when the opportunity offered.

Mr. JACKSON seconded the motion, which was carried unanimously.

The CHAIRMAN: I beg to thank you on behalf of myself and my colleagues for this kind expression of your confidence.

The proceedings then terminated.

The Cuba Submarine Telegraph Company (Limited).

The thirty-eighth ordinary general meeting of this Company was held at the offices, 58, Old Broad-street, on Wednesday, August 6th, under the presidency of Mr. Thomas Greenwood.

The SECRETARY (Mr. James Scott) read the notice convening the meeting; and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen,—The Directors are pleased to meet you again to discuss our affairs in which we are mutually interested, and to give you any further information that you may desire beyond that which is given in a concrete form in the report and accounts. The half-year has been a time of some little anxiety to the Board, but I think you will agree with us that it has been a by no means unsatisfactory half-year. You will remember that the half-year ended June last was the second half of the first year of the reduced rates, and, therefore, in making a comparison of the revenue you must please take into account the fact that it is compared with a period when the rates were 25 per cent. more than they have been during the period under review. Still, the receipts have kept up wonderfully well. You will have observed that they were £23,671 in June, 1889, and £23,206 in June, 1890, or a difference of only £465 between the two periods. Of course, a larger number of messages has been carried under the reduced rates, otherwise we should not have had such a large income; and notwithstanding that it usually occurs that when there is a larger number of messages there is also a larger amount of working expenses, it has not been so with us. Comparing the two half-years ended June, 1889, and June, 1890, there has been a reduction of expenses of £30, making the net difference on working only £435—that is to say, taking the income on the one side and working expenses on the other. It may be asked if the difference is so small, how comes it about that your dividend is reduced from 9 to 8 per cent.? The answer to that is very simple, namely, that we have now increased the divisible balance carried to the next half-year, while to pay the 9 per cent. dividend twelve months since the corresponding balance was considerably lessened. In the future, we shall compare what will be fairly comparable, that is to say, the income of 1890-1, as against that of 1889-90, both at the reduced rates. I am pleased to tell you that the traffic for the last month has increased by £150, as compared with the same month of the previous year; and if that rate should continue we shall have something like £900 at the end of the half-year, a sum sufficient to make up a dividend of 1 per cent. So that I think we may look forward to the future with satisfaction. There is, apparently, no reason to suppose that the dividend is likely to be reduced, provided we are not interfered with by outside influences. I use these words advisedly, because you are aware that a proposition is before the Spanish Government for making another line on the north coast, which, if made, would take away a large portion of the traffic we carry now. At the same time the Spanish Government have brought under our notice the rates which we are charging, with a view to ask us to reduce them still further. That representation is not made to us alone, but to all the telegraph companies which have their location in the Spanish Colonies. Having already made so large an abatement, it seems unfair to ask us for a large reduction now, more especially when the Government are consenting to the extension of another company's line almost parallel to our own. We are not disposed to make any abatement in our charges so long as that extension threatens us, nor unless other companies reduce their charges in the same way. We have made a smaller addition to our reserve fund than in the corresponding period of last year, for the reason that we had to lay out so much on our cables. We have it either in meal or malt. The expenditure has been unusual this half-year for repairs, because we not only had to repair the Batabano—Cienfuegos cable three times—which was broken twice by ships' anchors—but also to repair the 1875 cable between Santiago and Cienfuegos. It has been thoroughly repaired, so that we have a complete duplicate system between the latter two points; and when the new cable which is about to be laid down is finished, our cable system will be duplicated from one end to the other. I am pleased to say that considerable progress has been made in the manufacture of the cable. Already 60 knots of core are insulated, of which 50 knots have been passed by our engineers, and out of that number 18½ deep-sea and 4½ intermediate have been finished, and we may reasonably expect that this new line will be laid from end to end in a few months. I think I have given you all the information that we have at our disposal, and I will now move:—

"*That the report and accounts for the half-year ended 30th June last now submitted be received and adopted.*"

Mr. ALEXANDER F. LOW seconded the motion.

Mr. COCHRAN thought that it would be interesting to the shareholders to know how it was proposed to pay for the new cable which had been contracted for. There had been a somewhat heavy increase in their London expenses in the matter of salaries. The difference, it was true, was not very serious, but if the item were to assume a progressive character, and their business was to be interfered with by other regulations, he thought it was important that the Directors should take care that the expenditure should not grow unduly.

Mr. KING asked whether the French Company had made any progress with its threatened competing line on the north coast of Cuba.

The CHAIRMAN: No progress has apparently been made by the French Company. It is necessary that the Government should place in the possession of the Court certain papers before any progress can be made, and those papers have not been lodged. The whole thing has been in abeyance during the past six months, and I need scarcely tell you that no progress is good news for us. In answer to Mr. Cochran's question, I may say that the cable referred to is to be paid for in cash by four instalments of 25 per cent. It is not to be paid for in the shape of a rental. As we had the money in our pockets I am pleased to say that we were able to make fairly good terms. Regarding the salaries, I think I may say that we have arrived at the maximum. They are not likely to go beyond their present figure. There has been a small increase, but the Board considered it only fair to take into consideration the past services of the staff and the number of years they had been in the employment of the Company. The travelling expenses were incurred by the fact that it was necessary for the Secretary to go to Madrid—where he rendered very useful service to us—to oppose the application of the French Company.

Mr. COCHRAN: It is not an action at law, is it?

The CHAIRMAN: Yes, it is. The circumstances are these. The proprietors should know that the Spanish Government has made a royal order, which is practically an informal admission that it is desirable that an opposition cable should be laid; and that being so we brought an action, having previously made representations to them again and again on the subject before the order was passed. But having been passed we thought it best to bring an action against the Government to test whether they had a right to allow another cable to be laid to compete with our own.

The motion was agreed to unanimously.

The CHAIRMAN then moved:—

"*That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the Preference shares, and 8 per cent. per annum, free of income-tax, on the ordinary shares, payable on and after to-morrow.*"

Mr. NEIL BANNATYNE seconded the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. BANNATYNE, the retiring Director, Mr. A. F. Low, was re-elected to his seat at the Board.

Mr. John Gane, the auditor, was also reappointed, on the motion of Mr. C. W. PARISH, seconded by Mr. COCHRAN.

Mr. COCHRAN then proposed, and Mr. KING seconded, a vote of thanks to the Chairman and Directors, which was carried unanimously.

The CHAIRMAN, in reply, said that the small attendance of the shareholders was a fair indication that they had nothing to complain of in the conduct of the Board, who, he could promise them, would always do their best to protect the interests of the shareholders.

The proceedings then terminated.

The Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of the shareholders of the Maxim-Weston Electric Company (Limited) was held at Winchester House, Old Broad-street, E.C., on Thursday, for the purpose of considering, and, if deemed expedient, of passing the following resolution, viz.:—

"*That it has been proved to the satisfaction of this meeting that the*

Digitized by Google

Company cannot by reason of its liabilities continue its business, and that it is advisable to wind up the same, and accordingly that the Company be wound up voluntarily."

Mr. J. B. Gooding (Chairman of the Company) presided.

The CHAIRMAN, in moving the adoption of the resolution, said he was sorry to have again to meet the shareholders of the Company under unpleasant conditions. The Board, however, were in no way responsible for the disastrous position in which the Company was now placed. The Company had apparently been started under very unfavourable conditions, having a nominal capital of £40,000 or £50,000, on which only £14,000 was subscribed. The shareholders had already been made acquainted with the manner in which the money had been spent, and the Board now found themselves practically without resources. The shareholders were aware that one meeting had aleady been held for the purpose of ascertaining their feelings on the question, whether any further capital should be subscribed with a view to continuing the Company's business. Although £1,500 had been promised in the shape of debentures, that sum had not been sufficient to admit of the Directors going on with the concern; and accordingly the shareholders were now asked to consider the proposed resolution to voluntarily wind up the business. Before he submitted the resolution, he desired to place before the shareholders a number of figures concerning the Company's business in the past six months. On January 1st there was, roughly speaking, £5,000 in hand. On account of shareholders £30 had been received, and transfer fees to the amount of £5. Bank interest had amounted to £13 10s., and there were also other sums—for loan, £50; accounts collected and work done, £1,200; total, £1,303 4s. 5d., giving a gross amount of £5,700. The Board had paid on Directors' fees, £148; on salaries, £467; on wages, £336; on rates, taxes, and rent, £220; on gas account, £106; on travelling expenses, £28. 4s. 4d.; on petty cash, £125; on trading account, £2,255; on liquidation costs, and other expenses incidental to legal matters, £970; making a total of £4,658, and leaving a balance of £1,031, of which £1,000 lay at bank to the credit of the liquidators of the old Company. The Company's present liabilities amounted to £256. Cash in hand and amount to be collected amounted to £74. At St. Margaret Mansions the Company had an asset—whether it would be recoverable was a matter to be decided hereafter—of £300; so that although the Board came before the shareholders with a very bad state of affairs, the Company would go to the wall without taking anyone with it; in fact, it would pay all its liabilities. The Company, however, could not continue business. The Board have received one or two very encouraging letters from shareholders; but the result of the previous meeting had not been satisfactory, and the Directors, therefore, came forward with the present resolution.

A SHAREHOLDER: How do we stand in our lawsuit?

The CHAIRMAN: The action with Mr. Watt is still pending, but our solicitor states that it is likely to be completed in the present year, after the vacation.

Mr. COUCHMAN seconded the resolution.

The CHAIRMAN said it was probably desirable that he should offer a word or two of explanation as to the present position of the Company so far as related to the liquidators of the old Company. The property of the present Company had never been assigned to it by the old liquidators, so that any assets realised by sales of the Company's property, as the Board had been informed on the preceding Tuesday, were required by the old liquidators to be deposited at the Company's bank, pending settlement of the action with Mr. Watts. He could not altogether reconcile the wish of the liquidators with their action and statements in the past, because the Board were in the first instance told that £1,000 would cover everything required. Afterwards they were informed that £2,000 would be required; but now they were told that any liquidators of the new company selling its effects could not touch one farthing of the proceeds. The Company was therefore practically at the mercy of the old liquidators, and he was unable to congratulate the shareholders on the position in which they were placed—it was a position in which he did not feel at all comfortable.

A SHAREHOLDER: Who is responsible for the Company being at the mercy of the old liquidators? I hardly understand the matter.

The CHAIRMAN: I should say the solicitors of the present Company are responsible.

Mr. DAVIS, the Solicitor: Why, Sir?

The CHAIRMAN: Because they have never required the old liquidators to convey to the new Company.

Mr. DAVIS: That is not a fact, Sir; and I am surprised that you should say so.

The CHAIRMAN: We cannot fix the responsibility on any other person, but we shall be happy to hear what you have to say.

A SHAREHOLDER: I think we should have some explanation.

The CHAIRMAN: Mr. Davis says my statement is too bad; but, looking at the matter from a common-sense point of view, it is clear that the solicitors should see that this Company was conveyed to the present shareholders.

Mr. DAVIS contended that the Company had had everything. Anything the liquidators recovered was for the benefit of the present Company. But the liquidators must be indemnified by the new Company for the cost of the action in the event of its being lost. The shareholders could not make the liquidators personally liable for the costs and responsibility of the action.

The CHAIRMAN submitted that Mr. Davis was speaking entirely after the event. It could not be foreseen that the Company was coming to grief, and that only a few hundred pounds would be left for the expenses of the action. He considered that the solicitors should have seen that the effects were legally assigned to the new Company.

A SHAREHOLDER imagined that when the new Company was formed some agreement or contract was made defining the relation of the liquidators of the old Company towards the Directors of the new Company.

The CHAIRMAN observed that the liquidators would not assign, except under certain conditions. It was true that the interest of the old liquidators and the interests of the new Company were apparently identical; but the Company had as liquidators of the old Company representatives whose services on the Board had ceased to be required.

Mr. DAVIS said the liquidators had no interest in opposing the Company. If they won the action against Mr. Watts the sum of £4,000 or £5,000 would become the money of the shareholders, and that the Chairman's statement was worse than nonsense.

The CHAIRMAN said a contract in reality existed subject to certain conditions, which the Board had fulfilled. They were asked to place £1,000 to the credit of the old liquidators, but they now found that they could not deal with any of the Company's property. Subsequently a sum of £2,000 in all was required. After the present meeting the shareholders would see no more of him (the Chairman) in connection with the business of the Company. He had lost money by it, and he had made enemies by it.

Mr. DAVIS said the liquidators had been perfectly prepared at any time to assign, but in doing so they would have taken very good care that the shareholders deposited a sufficient sum to indemnify them in the case of losing the action. They would have been prepared to assign at any time, but as the assets of the new company had always been liable to the old liquidators, the latter in assigning them would have required security for costs to be incurred.

A prolonged discussion ensued, opinion being expressed by several shareholders that there was scope for business before the Company if a satisfactory solution of the difficulty could be found. Reconstruction was suggested; and Mr. NEWTON pointed out that as the Company could meet all its liabilities it was not insolvent, and that the resolution in that respect was inconsistent. The CHAIRMAN pointed out, however, that the Company could not continue business, and, finally, the resolution was adopted.

The CHAIRMAN proposed that Mr. Marks and Mr. Hodgson be appointed liquidators; and Mr. HAMBLIN moved, as an amendment, the appointment of Mr. Newson Smith. The amendment was defeated, however, and the remuneration to be paid to the liquidators was deferred for future consideration.

A vote of thanks to the Chairman closed the proceedings.

Keswick Electric Light Company (Limited).

The half-yearly meeting of this Company was held this week, and we have been furnished with the following report of the proceedings thereat:—

Mr. R. D. MARSHALL, J.P., occupied the chair, and said that there was no business to bring before the meeting, but he would be pleased to answer any question which any shareholder might put regarding the capital, expenditure, or working expenses. The balance-sheet would be placed in their hands at the end of the year. He might say that the accounts showed that for the first five months they had paid their way, though the income due from the consumers for that time was much less than it would be during the next six months. The light seemed very popular, and was quite satisfactory. They had many more lamps applied for than they could supply with their present machinery, and the question of enlargement of the station was being considered.

Messrs. Fawcus and Cowan's (the engineers) report was then read:—They said that the running of the machinery had been up to the present time quite satisfactory in every respect. The engine, which had been installed as a stand-by, had only been run twice during a short time, and then it was not on account of shortness of water for the turbine, but to help the turbine on the occasion of an exceptionally heavy load during the Keswick Convention week. It was found that the consumers were at present rather extravagant with the light, but it was hoped that as the novelty wore off they would be more careful to switch off all lights not actually in use.

A few questions were put by a SHAREHOLDER respecting the charge for the light, the CHAIRMAN remarking that the price was, as far as he had ascertained, lower than in any other town supplied by a central station.

After which the meeting terminated.

City and South London Railway Company (Limited).

The following is the report of the Directors of this Company (formerly the City of London and Southwark Subway Company) to the shareholders, at the twelfth half-yearly ordinary meeting to be held at Winchester House, Old Broad-street, E.C., on Tuesday, the 12th August, at 12 o'clock noon.

During the past half-year both of the tunnels have been completed, the whole of the permanent way laid, and the underground stations finished with the exception of tiling, painting, and other small matters. The surface stations and the lifts are rapidly approaching completion, and the hydraulic pipes and electric conductors are laid throughout.

At Stockwell Depôt the inclined road leading to the tunnels is finished and in use, the two engines and dynamos for the electric power are completed, and the third or reserve engine and dynamo is nearly ready; the three engines in connection with the hydraulic power for working the lifts are also ready, and the engine-house and carriage stores are roofed in. A portion of the rolling stock is ready for delivery, and it is expected the railway will be opened for public traffic at an early date.

The Bill for the extension of the line to Clapham has passed through Parliament and received the Royal assent. By it the name of the Company is changed to the "City and South London Railway Company."

The Bill referred to in the last report, and known as the Central London Railway Bill, was thrown out in the House of Lords. Your Directors will have to consider how far some of the advantages proposed by that Bill could be usefully provided by this Company without the objections urged against that measure.

To meet the wishes of many of the larger shareholders, notice has been given of a resolution to convert the share capital of the Company into Stock, so as to facilitate its transfer.

NEW COMPANIES REGISTERED.

BRITISH GAS LIGHTING IMPROVEMENT COMPANY (LIMITED).—Registered with a capital of £160,000, to carry on the business of mechanical, gas, and electrical engineers, and manufacturing chemists in all branches.

MULHOLLAND, MAUGHAM AND CO. (LIMITED).—Registered with a capital of £5,000, to take over the business of R. M. L. Mulholland and B. Maugham, at Ferryhill, Durham, trading as Mulholland, Maugham and Co., and to manufacture and deal in apparatus and things required in connection with electrical engineering, and in particular to construct and lay down cables.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 25th amounted to £5,114.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of July were £3,150, as compared with £3,003 in the corresponding month of last year. The receipts for the month of April, estimated at £3,600, realised £3,624.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts for the month of July are £2,016, against £1,677 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of July amounted to £54,224, as against £54,248 for the corresponding period of 1889.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic returns of this Company for the month of July are £46,367, as against £42,876 for the same period last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company are as follows:—Receipts in July, 1890, £25,600; January 1 to July 31, 1890, £156,000. Corresponding months in 1889 and 1888, £154,200 and £156,000 respectively.

NORTH METROPOLITAN TRAMWAYS COMPANY (LIMITED).—At the meeting of this Company, held at the Cannon-street Hotel on Wednesday, the Chairman said that the Directors had applied to the local authorities for power to use electricity, but at the same time they did not intend to experiment with the shareholders' money; but if anyone came forward and proposed to effect an installation, every facility would be given. The electric traction at Barking had been working satisfactorily, the General Electric Power and Traction Company having run 44,047 miles during the half-year, for which they were paid 4½d. per mile. A resolution declaring a dividend of 10 per cent. was carried.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—In the matter of Thomas v. the Notting Hill Electric Lighting Company, Mr. Maclean, Q.C., on Wednesday, stated before Mr. Justice Chitty that the parties to the motion, which was one for an injunction, had consented to an order on terms.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month ended July 31, 1890, amounted to £5,825.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the half-month ended July 31st show a decrease of £1 as compared with the corresponding period.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 1, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,921.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.—The dividend warrants for the interim dividend on the Preference Shares, of 6 per cent. for the half-year ended June 30th, were posted on Saturday last.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended July 31st amounted to £2,671, as compared with £2,672 in the corresponding period of last year.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

FACTORY.

JABLOCHKOFF'S DISTRIBUTION PATENT

(BEING A PATENT FOR "PRODUCING AND DIVIDING ELECTRIC LIGHT," No. 1996 of 1877.)

THE ELECTRICAL ENGINEERING CORPORATION, LIMITED

(STATTER'S) Are Proprietors of the above Patent, and Warn the Public against Infringement. (UNITED).

The following are Licensees:—

Brush Electrical Engineering Company, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.

3, PRINCE'S MANSIONS, VICTORIA STREET, WESTMINSTER.

PERCY E. SCRUTTON, *Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 639.—Vol. XXV. FRIDAY, AUGUST 15, 1890. Price Fourpence.

NOTES.

We learn from our New York correspondent that the Postal Telegraph scheme is again before the United States Congress, but again with as little prospect of any serious progress being made in that direction. It surprises us somewhat that the experiment has not been tried on a comparatively small scale by one or other of the States, each of whom possesses a sort of independent government. But we presume that the radical objection to this much-needed undertaking is the same for the separate States as for the whole country, namely, the political character of all their executive and administrative departments. For the telegraphs certainly a change of officers, such as takes place in the Post Office and other public departments, with every change of President would be an impossibility; and until the United States consents to reform its political institutions any change in the status of the telegraph service is not to be hoped for. For a nation that prides itself on being ahead of the universe the confession that "we are not yet ripe for such a radical change" is a very humiliating one, and one which helps us to regard with complacency the less democratic institutions of the old world, where professional politics have not yet invaded the public service.

Candid critics will probably acknowledge that, so far as regards simplicity and the elements which bear on the question of efficiency, the design of the new American dynamo which we illustrate this week is a good deal behind that of the English one which accompanies it. The dynamo of Prof. Elihu Thomson was mentioned by our American correspondent in his New York letter of last week. The description reminded us at once of Mr. Mordey's work, but we were hardly prepared to find in the two leading American electrical journals, and announced as extraordinary and revolutionary, an illustrated account of a machine the principle of which resembles so closely one of the forms proposed by Mr. Mordey. The English inventor described a number of methods of constructing dynamos in which the magnetic induction through the armature coils is altered by means of a moving "keeper." An interesting feature in the English design is that the arrangement is such that no back volts are set up in the field coil, although it is engaged in magnetising a laminated iron structure, all the parts of which are undergoing violent periodic changes of magnetisation. We understand that, in spite of its great simplicity, Mr. Mordey did not put into practice that particular design, which is one of many changes which he rings on this theme in his patent, because there is iron in the armature. And with regard to simplicity, it will be remembered that he followed up on the same line of development, and showed at the Institution of Electrical Engineers a model of a still simpler form of machine. We are not so convinced of the evil effects of iron in the armature as is Mr. Mordey, although it must of course be acknowledged that absence of iron in the armature means reduction of losses. His arrangement of the field coils and magnetic circuit is much superior to that of Prof. Thomson, whose design includes a magnetic circuit to which many objections may be raised.

It is somewhat strange that since the chief object of electric lighting is to produce illumination, the subject should be so little studied; and it is to be hoped that we may before long have definite specifications of the amount of illumination that is desirable for different purposes and localities. We have analysed in another column some of the recent work of M. de Nerville, who advocates the "bougie-metre" as a unit of illumination. This is the same as the "deci-lux," the tenth of the "lux," which was suggested in 1884. We take from the *Gas World* of last week an abstract of an article by Prof. Leonhard Weber, of Breslau. This abstract, which has apparently suffered considerably in abridgment, gives some interesting estimates of the relative brightness of various sources of illumination and of illuminated surfaces. It would appear that we have less occasion to grumble about the inability of our eyes to detect a difference of less than 2 per cent. on a photometer screen (and many of us cannot recognise 4 or 5 per cent.) when we find that the range between a sheet of printed paper, so lighted that it is just possible to be read, is some thousand millionfold less bright an object than the noonday sun. Prof. Langley, if we remember rightly, has arrived at a similar estimate. In connection with the same subject, an account of the arrangement of both arc and glow lamps in textile factories will be found in another column, and a description of the Siemens-Violle standard lamp.

It is very difficult to determine the degree of accuracy with which photometric measurements of illumination should be carried out. There is more than one serious obstacle to anything like the precision that is aimed at in most physical measurements. The ratio of the rays transmitted by the red and by the green glasses compared with sunlight does not, of

Digitized by Google

course, measure the relative amount of red light and of green light of the sun, but of the standard lamp or candle used in the photometer. But a new difficulty presents itself which does not appertain to the instrument or to the sources of illumination which are compared by it. Prof. SCHUSTER, in the last number of the *Proceedings* of the Royal Society, describes some experiments made with Lord RAYLEIGH'S colour box. He submitted to a considerable number of persons a pure yellow image, from the D part of the spectrum, and a compound yellow composed of a full red near C, and a green of wave length 562. By means of a Nicol prism each person could mix the red and green components together in any proportion; and they were asked to make the compound yellow match the simple colour. By plotting the number of observations for different proportions, a curve of the nature of a probability curve, but with some marked characteristics, was determined. The apex should show the normal proportion. This apex is not well defined, and the curve is irregular, but the remarkable point about it is its extraordinary range. One observer required 2·8 times as much red as green to make the match, while another took five times as much green as red to produce the same tint. Under these circumstances anyone using a photometer in which coloured glasses are used should satisfy himself that his eyesight does not differ much from the normal. We would suggest that Mr. GALTON should add a colour box to the instruments at the public anthropometrical laboratory at the Science Collection at South Kensington.

THE issue of the prospectus of a Sectional Boiler Company reminds us that a thorough comparison of the advantages of sectional and Lancashire boilers has never yet been made. The Babcock-Wilcox boiler has been largely employed for electric lighting purposes, and some of its merits are obvious, while there are points in which it cannot compare with a shell boiler. We have yet to hear a complete Paper on the subject at the Institution of Civil Engineers, and we hope that such a Paper may be prepared by some engineer who has had ample experience of both kinds. The elaborate report of Mr. LONGRIDGE, which appeared in *Engineering* last month, describing a trial of a Babcock-Wilcox boiler, is of little use for purposes of comparison, and the author did not undertake to offer criticisms of any moment; indeed, the Paper concludes with the observation that the balance sheets of the tests call for no remark. This is leaving half the work undone. The report has given rise to a few letters in the columns of our contemporary, but it is to be regretted that up to last week they do not amount to a discussion. The new Sectional Boiler Company sets out 27 advantages, of which 16 are comparisons with other tubular boilers, and the remainder relate to Lancashire boilers. Statements of this kind in a prospectus do not carry much weight, but they may at least be taken as indicating the direction in which advantages may be found. The Babcock and other tube boilers have been used largely in America, and Bellville boilers are very commonly employed in France. We believe this may be accounted for to no small degree by the facility which such a boiler offers for transport when packed in for delivery. It can be handled in small parts, and it is easily erected. These advantages do not carry so much weight in this country where the railway companies are quite familiar with the carriage of boilers by rail and road. One of the engineers whose report is quoted in the prospectus, says that the new patent boiler gave results "far in excess of anything within my experience, certainly 15 per cent. better than the ordinary Lancashire boiler . . . and 32 per cent. better than that obtained by Mr. LONGRIDGE . . . with a Babcock-Wilcox." This is rather a side cut at the well-known steam generator. No mention is made of the kind of Lancashire boiler; and considering how very much these vary on account of the different conditions of working and use, it may be doubted whether the new patent will do better duty than the best productions of Galloway.

IN noticing the last number of the *Quarterly Journal* of the Massachusetts Institute of Technology, we drew attention to the splendid equipment of the engineering laboratories of that Institute. In the Notes will be found an abstract of an account of the Electrical Engineering College of Princeton, New Jersey, and a brief description of the course of instruction given there. From the clever illustrations in our American contemporary, the laboratories and shops do not appear to be very large, and we doubt if they could comfortably accommodate the students of the Finsbury Technical College, who manage to work with a minimum of elbow-room. The text-books include the works of MAXWELL, CUMMING, STEWART and GEE, KOHLRAUSCH, SLINGO and BROOKER, GRAY, S. P. THOMPSON, KAPP, and Dr. FLEMING'S "Alternate-Current Transformer," the latter being "read for four hours a week for half the year."

West Cowes.—The Local Board recommend that sanction should not be given to the application made by the Electric Light and Power Supply Corporation to the Board of Trade for providing light in this district.

A New Telpher Line.—The Telpher Railway at East Pool is now complete. A trial was made on Friday last week in the presence of a large number of persons interested, when its working was declared to be perfectly satisfactory.

Electric Lighting in Berwick.—The Northern Electric Light Company intimated on the 12th inst. to the Berwick Urban Sanitary Authority their intention to apply to the Board of Trade for powers to supply electric light in Berwick.

Electric Tramway without Grooved Rails.—Messrs. Merryweather and Sons, writing to the *Star*, say that some important experiments are taking place at their Greenwich works in connection with this subject, whereby the grooved rails are dispensed with.

Liskeard.—At the quarterly meeting of the Town Council on Tuesday, it was decided "that a Committee be appointed, with powers to incur expenditure in getting the opinion of experts in lighting the town either with gas or electricity, and the cost not to exceed £20."

Accumulator Tramcars in America.—The Union Electric Car Company have been running cars weighing six to seven tons, with a charge that will drive the vehicles for 30 to 40 miles. The trolley wires and feeders and turnouts are being recognised as unsightly and dangerous in Boston.

Electric Lighting at Konigsberg.—The work of laying the mains is now nearly finished, and connections with the houses will be commenced at once. The Mayor has decided that the lighting shall start on October 7th. This will only extend to the central portion of the city, though that of the lower town will follow in the course of a few weeks.

Digitized by Google

Budapest.—Messrs. B. Egger and Co. have in view the lighting of the block of buildings bounded by Dorothea, Wurm, and Valerie-streets, and Franz Joseph's Platz. The first installation will include plant to the extent of 300 horse-power, together with the usual battery of accumulators.

Llanelly.—At the monthly meeting of the Local Board of Health, on Tuesday, it was resolved that the resolution of the Board giving permission to a local company to apply to the Board of Trade for a licence to light certain districts of Llanelly with electricity be rescinded, and it was subsequently decided that the Board apply for powers themselves.

The Gas of Cork.—Mr. Denny Lane, Secretary of the Cork Gas Consumers' Company, writes to point out that the remarks of the Judge to which reference was made in last week's issue, related to some Argand burners which were suited for burning cannel gas, but were unfit for ordinary gas. The Cork gas is 16½ candle, instead of 14 candle, according to the local Act of Parliament.

Glasgow Electric Tramways.—At the Glasgow Town Council on Wednesday it was stated that a letter had been submitted from the Electric Tram Car Syndicate bringing under the notice of the committee their system of electric traction. After some discussion it appears that it was decided to acquire the Ibrox Tramway Company's lines, and work them in connection with the Glasgow tramways.

Berlin.—From the *Elektrotechnische Zeitschrift* we learn that the lighting of the suburb of Grunewald by the Kurfürstendamm Company will be at once proceeded with, although a more suitable site for the central station is to be desired. The streets are to be lighted with incandescent lamps, 12 amperes. The total cost, inclusive of buildings, is estimated at 300,000 marks (£15,000).

Municipal Lighting at Kassel.—At Ostheim's mill, which, as we announced in our last issue, has been purchased by the authorities, there is available, besides the water power, steam plant to the amount of 120 horse-power. These will be used to drive alternators, and at the central station in the town alternating-current motors will drive continuous-current dynamos, which will supply the lights and charge accumulators.

Coal-cutting Machinery.—Several patents have been taken out in the United States lately, by Van Depoele, for coal-cutting machinery, but all of them are of a reciprocating character, a so-called magnetic piston working in a number of coils. It is very unlikely that this plan will give satisfaction, for though it may directly give the required motion of the tool, it is the wrong way to produce motion on a large scale by electricity.

Fulham.—The Vestry has resolved to take the necessary steps through the Lighting Committee to prevent any of the companies obtaining powers to supply the electric light in Fulham. The application of Mr. S. Morse, on behalf of the Chelsea Electricity Supply Company (Limited), for permission to obtain a Provisional Order, authorising them to run electrical trams through the parish along the Fulham-road and King's-road, has not been acceded to.

Telegraph Clerks.—Sir H. Maxwell (on behalf of Mr. Raikes), in reply to Dr. Farquharson, said that much attention had been given to the question of overtime, with every desire to lighten its incidence; but no one, either on the part of the Post Office or on the part of the officers themselves, has been able to suggest any practicable scheme for getting rid of these duties. This matter formed an element of consideration in improving the pay under the scheme recently issued.

Electric Motors in America.—The Rochester Brush Company, driving dynamos from the falls of the Genesee river, have 500 motors at work. 108 tailors' shops are supplied at the rate of £3. 15s. per annum for ⅛th of a horse-power. Ventilating motors are run continuously from June till October for £3. 2s. 6d. One horse-power per day is supplied for a shilling. Two horse-power per annum, £25; five horse-power, £52; eight, £83; and 15 horse-power, £146.

Telephonic Communication with Harbours and Roadsteads.—Manilla was to have made the first move in this direction in the East, although the matter seems to have been spoken of at Madras. *Indian Engineering* hears that the Telephone Company at the Port of Manilla has taken measures to open a floating station in the harbour, so as to admit of vessels communicating with the city, thereby benefiting people on board by saving them the trouble of going personally ashore.

Telephones on Ben Nevis.—Mr. Erskine Mudehead has offered to erect at his own expense a set of "Ader" telephones on Ben Nevis. These will connect the summit and the low-level observatories, but at present the Telephone Companies block the way. It often happens that for two months communication with the summit of Ben Nevis is cut off, so that the new method of intercourse between the occupants of the observatory and Fort William will be very welcome.

Harrogate Town Council.—A quarterly meeting of the Harrogate Town Council was held on the 12th inst. A number of companies having given notice to the Corporation that they would seek powers for the purpose of lighting the town with electricity, the Town Clerk reported that the notices were in the hands of the borough solicitor, who was instructed to take all necessary steps with regard to the same, in order to prevent the companies obtaining the powers which the Corporation hope in the near future to obtain themselves.

The Life of Lamps.—A very notable case of lamp endurance is reported by the *Electrical World* from Albany, Georgia, where, in a restaurant using nine 32 candle-power lamps, and one 50 candle-power, but one new lamp has had to be put in for a year and a-half, or during an actual lighting of 3,500 hours. If this record is authentic, the lamps in question certainly deserve their name of "Edison High Economy"; but there is no mention of the voltage used. A slight variation from nominal voltage explains many phenomenal records.

Lighting of New York.—It appears from a report upon the tenders for lighting the streets of New York by electricity that there was no regular combination among the electric companies to keep up the prices, as far as could be discovered by any examination of the figures. The fact remains that all the tenders were very high, and the question of reverting to gas in a number of streets is being considered. The reason is no doubt due to the removal of so many overhead wires, and the absence, at present, of the necessary conduits under the streets.

Telegraphs in China.—It is announced with an appearance of authority, says *The Times*, that the Telegraph Convention between the Chinese telegraph administration and the Great Northern and Eastern Extension Cable Companies, for maintaining a uniform rate for messages between China and the rest of the world, will not now be ratified. It appears that Li Hung Chang (like the late Marquis Tseng) has thrown his weight against the Convention, on the ground that it would be derogatory to China to give up her independence in this matter in return for an annual subsidy.

Utilising Scrap Steel Rod.—The Thomson Electric Welding Company has built a machine especially for the welding of scrap steel to be drawn into fence wire. The Illinois Steel Company has tons and tons of steel rod scrap which it has been obliged to melt over in order to utilise it. The Company invited the Welding Company to experiment with this scrap, which it has done successfully, and it will now build machines for practical work. The machines will yield the company $1,200 (£336) advance minimum rental, and a royalty of 1 cent. per weld during the life of the patents.

The Lighting of the House of Commons.—In reply to Sir G. Campbell, who asked the First Commissioner of Works if he would arrange before next Session to put shaded electric lights in the roof of the House so as to save members from the heat and glare of the gas in the long winter nights, and make the nearest possible approach to daylight, Sir H. Maxwell said, on Friday last, that the electric light was tried in the roof of the House some time ago, but the results were not satisfactory. The present gas lights were connected with the ventilation, and it would be inconvenient to dispense with them.

Electric Traction at Hammersmith.—In spite of the wishes of the adjoining Vestries of Chiswick and Brentford, the Vestry of Hammersmith continue to maintain a hostile attitude to the use of electricity on the tramway in that district. Mr. Lineff abandoned the slotted conduit on which the first ostensible objec-

Digitized by Google

tion by the Vestry was based. The system which has recently been described has been sanctioned by the London County Council and the Board of Trade, and by the Vestries concerned, but, according to a characteristic article in the *Star*, which broadly hints that such things are arranged by fees to the vestrymen, further progress is still blocked by the local authority.

Is Electricity Manufactured?—The Courts of Pennsylvania are trying to settle the question whether or not electric light companies are manufacturing companies. Manufacturing companies, says the *Manufacturers' Gazette*, of Boston, are exempt from taxation in that State under certain conditions, and the Courts hold that electric light companies do not manufacture anything, that electricity is not manufactured—they do not manufacture light. The question will probably be carried to the highest Court before being settled. As manufacturing consists of increasing the value of raw material, electric light companies do not come within the meaning of manufacturing.

Two Large Electric Cranes.—Two travelling cranes, which in some respects will be unlike any others yet constructed, are to be put into the Baldwin Locomotive Works by Messrs. Wm. Sellers and Co. They are, according to *Iron*, each to be of 100 tons capacity, with a span of 75ft. 4in. and 336ft. run, and are to be driven by electricity. The maximum speed of the bridge travel will be 200 per minute, trolley travel 50ft. and 100ft., and main hoist speeds 5, 10, 20, and 40ft. per minute. It is the intention to handle and transfer from one track to the other the heaviest locomotives complete by means of these cranes, while for handling parts and lighter loads there is an auxiliary hoist capable of lifting 1,000lb. at a speed of 100ft. per minute.

Telephone Communication with Telegraph Offices.—In France, as in England, there are a great many hamlets and villages to which the network of telegraphs has not yet extended, and persons living there are obliged to pay a heavy fee for the carriage of a despatch from the nearest telegraph office. In France a measure has, according to the *Pall Mall Gazette*, just been decided upon which will reduce this fee to 2½d., and at the same time almost entirely do away with the delay occasioned by the carriage of the despatch by hand. All communes which have not a telegraph office are to be connected with one by telephone, through which the despatches received by telegram will be forwarded verbally, the despatch being later on ent by post.

St. Moritzbad.—The scheme which has been abandoned at this place by the advice of the well-known engineer, Mr. Uppenborn, who was consulted as an expert, as not being suitable for the case, was the project for using four continuous-current high-speed dynamos, of 2,000 volts each, coupled together in series, and not the alternating-current proposal, as erroneously stated in a Note last week. The Editor of the *Elektrotechnische Zeitschrift* is good enough to inform us that the plans of the firm of Stirnemann and Weissenbach, of Zürich, with some modifications, have been adopted. Three Girard turbines, with horizontal shafts, are coupled direct to alternate-current machines, made by Messrs. Ganz and Co., of Budapest. These give a pressure of 3,000 volts, and the current is conveyed to the hotels by a copper circuit of about 9 kilometres, and is there transformed to 100 volts.

The Thomson-Houston Electric Coal-cutting Machine.—The Thomson-Houston Company has put one of their coal-cutting machines into operation near Osceola, Penn. The cutter, which is operated by a five horse-power motor, is nearly a mile from the generating plant. The cutter itself consists of an iron frame 24in. high, 8ft. 6in. long, 30in. wide. Nine auger-shaped drills similar to those now used in mining are placed in the lower part of the frame. Between each drill is a steel cutter bar which cuts all coal left between the holes drilled by the auger bits. On the under side of each cutter bar are attached several scrapers, which hang loosely and pull all the coal back as soon as it is cut or drilled, keeping it out of the way and making the opening clear. The height of the cut is four inches, and the machine makes two cuts in five minutes. The weight of the complete machine is a little over half a ton. The motors are wound for but 220 volts pressure. The capacity of the machine in question is 160 tons of coal per day of ten hours in a four-foot vein

Electric Light in Churches.—Arrangements for the complete lighting of the Church of St. Jude, South Kensington, by electricity have just been concluded between the vicar and churchwardens and the House-to-House Electric Light Supply Company (Limited), of Richmond-road, West Brompton. The installation is to consist of 275 incandescent lamps of 8 candle-power, the existing gas fittings being utilised in nearly every instance for the distribution of the light. The nave, for example, will be lighted by 144 lamps, 12 lamps to each of 12 coronas; the chancel will absorb 66 lamps, 30 on two standards in front of the altar, and 36 on four standards for the choir stalls. Eighteen lamps will be distributed on brackets round the galleries, and 28 for the lighting of the aisles. There will be five lamps within and about the organ, one of them being a portable lamp, to facilitate tuning operations, &c., without the danger involved in the use of matches and of exposed gas burners. The remaining lamps go for the lighting of the vestry, gallery stairs, &c. The whole installation will be completed, connections made with the company's mains, and the current supplied within about a month.

Hammersmith Electric Lighting.—The Law Committee of this Vestry had under consideration a letter from the Board of Trade, enclosing copy of a letter they have received from Woodhouse and Rawson (Limited), and asking for the observations of the Vestry upon the matter. The Committee recommend the Vestry, in answer to the letter from the Board of Trade, to consent to the application of Messrs. Woodhouse and Rawson to purchase from the West Middlesex Electric Lighting Company the undertaking authorised by the Fulham District Electric Lighting Order, 1884, subject to their agreeing with the Board of Trade, and the Vestry to be bound by and subject to all the latest provisions required by the Vestry, and also to their undertaking to apply in the next Session of Parliament for a Provisional Order embodying all such provisions; and also subject to their paying all legal and Parliamentary costs already incurred by the Vestry in connection with previous applications and to be incurred during the next Session in connection with the proposed application; and in the event of the order being sanctioned, the works to be proceeded with within three months after such sanction.

Telephone Trunk Lines.—A telephone map of the north of England is covered with lines representing trunk wires between the various towns, and it is possible for conversation to be carried on between nearly all towns of importance. Out of Manchester there run, says *Engineering*, no less than thirty-five wires: four to Glossop and Sheffield; five to Stockport, and thence in decreasing number to Macclesfield, Congleton, Newcastle-under-Lyne, Birmingham, South Wales, and London; four to Warrington; nine to Bolton; three to Bury; seven to Middleton and Rochdale; three to Oldham. There are fifteen wires out of Liverpool; twenty-one out of Bolton; nine out of Preston; sixteen out of Blackburn; twelve out of Todmorden; twenty out of Bradford; eighteen out of Leeds; sixteen out of Dewsbury; fifteen out of Sheffield; fifteen out of Derby; twelve out of Nottingham; thirteen out of Stockton; twenty-three out of Newcastle; and many others. The London subscriber to the telephone will say that things must be better managed in the North than in the metropolis to render it possible to hear over such long distances. However, he will soon have an opportunity of putting the matter to the test, for London will be joined within the next few months to all the towns we have mentioned.

Lifts worked by Electric Motors.—At the Demarest Building, Fifth Avenue, New York, are two lifts, capable of raising 16¾ cwt. 110 feet per minute. The motor is so coupled to the lift gear that it starts and stops with the winding machinery under control of the attendant in the car, thus forming a single apparatus, free from jerky and irregular running of detached gearing, as when worked by belts. The controlling rope is connected with the switch and the brake by means of the steel bar running across the base of the apparatus. An indentation in this bar (into which a wheel supporting the brake-weight settles when the current is turned off) makes simultaneous the action of brake and switch. When the switch is at centre the brake is lowered into the

Digitized by Google

indentation in the bar, and the weight, applied directly to the armature shaft, stops the motion of the armature. When the steel bar is moved in either direction the current is turned on and the brake raised. The current is supplied from the Twenty-sixth-street Edison station at 220 volts. The armature makes 800 revolutions per minute, and is connected by worm gearing to the winding-drum, which revolves ten times a minute. Heating and "burning out" have been guarded against in the construction of this machine, and an indicator is employed which shows the operator in the car the position of the controlling and reversing switch on the motor.

The Kimberley Electrical Tramways.—The opening ceremony of the Kimberley Electrical Tramway took place on the evening of July 17th, and is thus described in the *Diamond Field Mail Summary*:—"The ladies having taken their seats inside the car, the imposing-looking vehicles moved majestically out of the depôt guided only by the delicate hand of Mrs. John Gibson. A bottle of champagne was broken on its ample front as it emerged from under cover." . . . "In the early part of last year Mr. John Gibson proceeded home and travelled throughout England and the Continent with the object of finding out the best system of propulsion by electricity. After considerable difficulty he found the firm of Messrs. Mather and Platt, of Manchester, who guaranteed that their cars would run by this system, and the Messrs. Gibson accordingly arranged with that firm to send out a gentleman who would erect the required machinery." English coal at £9 to £11 a ton makes the cost of working by electricity very great on the diamond fields, but of course there is a saving in horses. A shed is provided with long substantial-built tables for the batteries, the car being run in between these tables for changing and putting in fresh batteries. The engine is one of Marshall's compound, with all the latest improvements, and drives one of Mather and Platt's Edison-Hopkinson dynamos. In the car shed is a large acid bath for mixing the acid, lined with thick heavy lead and wooden casing outside, and iron tanks for catching rain water for the use of the batteries.

Horticulture by Electric Light.—In the botanical department of the Cornell University there have recently been made some experiments in the cultivation of plants under electric light, which appear to give results differing from those which Sir W. Siemens obtained. A number of flowers and of vegetables were placed where the rays of powerful electric lamps fell upon them night and day, and their growth is compared with that of others of their own species planted at the same time and under similar conditions, except in the matter of light. The first and most noticeable effect of this treatment is an enormously increased rate of growth. The plants which are lighted seem to work day and night, and to become especially luxuriant in foliage. The vegetables shoot forward with great quickness; peas, for instance, become in a few weeks two or three times as tall as their brethren living by common daylight; and the same thing is true of all the plants. When it came to seeds or fruit of any sort, the matter was entirely different. Here the plants, which had grown slowly and by daylight, were ahead. It is true that the pea which grew by electric light came to bearing much sooner than the other, but its hastily-made pods had very few peas, often only one, and these of an inferior quality. In every instance the reproductive powers of the plant seemed to have been most strongly affected, being sacrificed to mere foliage. It will be remembered that in Sir W. Siemens' experiments, the direct rays of the arc light tended to wither leaves, but this effect was modified when glass was interposed.

The National Electric Light Association.—At the semi-annual Convention to be held on August 19th the following are the subjects of Papers which will be submitted and discussed:—Electrical Industries and the World's Columbian Fair, J. P. Barrett, Chicago; Electric Light as Supplied to Steam Railroads, W. H. Markland, Altoona, Pa.; Standards of Economy in the Generation of Power and Steam under Best Conditions, Editor of *Power and Steam*, New York; Triple Expansion High Speed Engines for Central Station Work, Mr. Williams, Beloit, Wis.; the Model Boiler-room and the Duties of a Fireman, Jarvis B. Edson, New York; Ferranti Station, London, England, Caryl Haskings, Lynn, Mass.; the Proper Care and Management of Alternating Currents, T. Carpenter Smith, Philadelphia; Distribution of Energy by Alternating Currents and Transformers, and the Proper Method of Proportioning Conductors, A. L. Rohrer, Lynn, Mass.; the Proper Basis for Determining Electric Motor Rates, H. L. Lufkin, New York; Actual Cost of Furnishing Arc Lighting (1,200 and 2,000 candle-power lamps) under the Best Possible Conditions, J. C. Ayer, St. Louis; Municipal Ownership of Electric Lighting Plants, M. J. Francisco, Rutland, Vt.; Accidents in Electric Lighting Stations and Plants, Prof. Charles R. Cross, Boston; Care and Labour in Electric Light Stations and its Value, A. J. De Camp, Philadelphia; How Can the National Electric Light Association Best Serve the Interests of Central Station Companies? C. R. Huntley, Buffalo, New York. Reports from the several committees will also be submitted.

The Dennis Iron Tubular Telegraph Pole.—This pole has been designed with the view of providing a strong telegraph pole, which can be, by unskilled labour, easily fixed. The pole consists of three parts:—(1) The base socket of cast-iron, with strengthening webs on the outside, and a pointed end which can be driven into the ground, preferably by means of a small "monkey." For this purpose a gun-metal plug is supplied, which fits into the top of the socket, taking the force of the blow and preserving the casting from injury. (2) The taper tube of wrought iron, slightly coned at its lower end, and fitted at the top with wrought-iron carriers for the usual earthenware insulators. (3) The cast-iron ornamental cap, which forms the joint between the base and the tubular pole. The base socket has a small spigot cast thereon, and the cap has a spiral groove cast therein, in which the spigot can travel. Between this cap and the upper portion of the pole is a liner of asbestos or india-rubber, for the purpose of giving a better grip to the joint. The method of erection is as follows:—The base socket being driven into the ground down to the widest portion of the webs, the cap, with its liner of asbestos, is dropped over the top of the pole. The tube is then lifted on to the socket base, and the groove in the cap is brought into position with the spigot on the base, and by means of a long-handled spanner fitting over the hexagonal portion of the cap, the latter is turned as far as possible. As the spigot is thus made to travel up the spiral groove in the cap, the asbestos liner is compressed, and the whole forms a tight joint. The arms carrying the insulators are clipped round the top portion of the tube, and the pole is complete.

Thunderstorms.—Five persons sought shelter under a tree near Nottingham during the storm on the 11th inst. A flash of lightning was seen, and the whole of the persons standing under the tree were struck down. A man aged 50 and a boy of 11 were killed, and the other three persons were found to be seriously injured. One was unconscious, but hopes are entertained of his recovery. His son and another lad received shocking injuries to their feet. At Mansfield a man aged 69 was struck dead by lightning, and the tree under which he had taken shelter was also damaged. The seam of one of the trousers' legs had been cut open by the lightning, but he did not appear to have sustained any injury except to one of his feet. The residence of the manager at Laird's shipbuilding works was struck by lightning. It demolished a chimney, and passed down into one of the sitting-rooms, which was almost completely dismantled. The mantelpieces were hurled into the middle of the room. In another house the pictures were cleared off the wall, and all smashed. On Monday a flash of lightning made a hole in the roof of a house at Harwich. According to the *East Anglian Daily Times* it entered near the chimney, and passed through the upper room and struck the bell wires, severing them. Tearing away and scorching the paper, it continued its way along the wires to the second flight, and at each place where it met with any resistance it broke the wires and scorched the paper on the walls. It again passed to the lower floor by the wires, and in the downstair passage melted a gas-pipe, and then exploded like an immense quantity of crackers. The connection of the bells to every room but one was completely severed, and the wires left hanging down the walls.

Water Power of the Rhone at Geneva.—Colonel Turrettini, the engineer of the St. Gothard Tunnel, has made a report on the works which have been carried out at Geneva under his superintendence. The left arm of the river, where the island divides it, is provided with 20 turbines, yielding 4,400 horse-power. One half of these are in use. A hydraulic service, with a head of 460ft., is supplied by pumps driven from this source. Last year there were 216 industrial motors, with a total output of 1,565 horse-power, the minimum being ⅓ horse-power for sewing machines, up to 625 horse-power for the electric light company. The total cost of the work has been £284,000. The income is said to be—for power, 2,500 horse-power for 3,000 hours at 0·08fr., 600,000fr. (£24,000); 2,500 horse-power for 5,000 hours at 0·08fr., 1,000,000fr. (£40,000). For light, 15,000 lights at 30fr., 450,000fr. (£18,000). Total income, 2,050,000fr. (£82,000). The following particulars with regard to the water-power electric lighting station at Geneva may prove of interest. The concession was granted by the town in 1887 to the Société d'Appareillage Électrique, and the station came into operatfon in February, 1888. The plant comprises three Weibel-Briquet turbines driving 2,100 horse-power Thury dynamos, and one 25 horse-power turbine driving two small Thury machines. The distribution is carried out on the Edison 3-wire system. While the concession lasts, that is to say until the end of 1895, the street lights are to be supplied at the following rates: 16 candle-power lamps at ·475d. per hour, 10 candle-power lamps at ·38d., and 8 candle-power lamps at ·285d. per hour. At the end of last year 5,000 lamps had been connected to the Company's mains, current being supplied at the rate of 5½d. the kilowatt hour. The water is supplied to the company by the town at a charge of ·19d. the cubic metre, the minimum amount to be charged for in any one year being 400,000 cubic metres (88,000,000 gallons). In 1889 1,120,000 cubic metres (246,400,000 gallons) were consumed.

The Fire Alarm System of Jersey City.—A system of fire alarms has been introduced by the fire department of Jersey City, which could be used with advantage, it would appear, in towns where there is no regularly paid force of firemen. The peculiarity of the system consists in ringing tower bells in different parts of the city by means of electric signals from alarm boxes placed as usual in conspicuous places in the public thoroughfares. In Jersey City there are four towers, from each of which every fire alarm is sounded, according to the number of the box whence it has been sent. The electric service also rings the gongs in all the fire-engine houses of the city. If a fire occurs a box is opened, a handle pulled down, an electric circuit broken, and the armature of an electro-magnet is released, starting the mechanism. A metal drum rotates under a spring that presses on it. The circuit, including the magnet, is completed through this spring. A number of notches are cut in the periphery of the drum. As it rotates, the spring drops down into these notches, and each time that it does so breaks the circuit. Each time that this occurs the bells in all the engine houses in the city ring, and the four bells in the towers ring the same alarm at a slower rate. The notches are cut differently for each box, so as to form by their combination and spacing a special signal. When a box is rung, its "makes and breaks" are transmitted to the central electric station, where they actuate an automatic recorder and repeater. By one part of this apparatus the signal is recorded by holes punched in a strip of paper or "tape," and at the same time is repeated by relay action to all the engine houses. The same apparatus by its second division regulates the current to the four bell towers. Like the other circuits, the bell-tower circuit is kept closed. The repeater, therefore, has to open the circuit once for each ring corresponding to the box number, and has also to space these properly to express the two digits that generally compose this number. It has also to perform one additional function. The signals are sent out to the engine-houses at the rate of a beat a second. This speed would not answer for the large bells, and the repeater sends out the signal at a slower rate for them. The tape is fed at speed regulated for one break per second, through that part of the apparatus which perforates it, and sends out the signals to the engine-houses. Next, the paper is fed through the part of the mechanism which operates the tower bells. The tape passes through this at one-half the former speed. A flat spring presses upon it and keeps the circuit closed as the paper holds it up in contact with a terminal. When a hole comes beneath it, its point drops into the hole, and the circuit is broken for an instant, and the bells ring once. Thus, an autographic repetition at reduced speed of the engine-house signals is given The bells are rung by mechanism actuated by a descending weight of 3,000lb. When the circuit is closed an armature is held attracted by the magnet, and the motion is arrested. When the circuit is opened, the falling away of the armature releases a detent, and the ratchet wheel holding the weight begins to revolve. The action of a lever connected to two pawls, which engage at regular intervals with the ratchet wheel as it revolves, causes a clapper to strike the bell.

Electrical Engineering College of New Jersey.—In a recent number of the *Electrical World* there appears a description of this College, which has been recently established at Princetown, and is designed to give a thorough training in both theoretical and applied electricity. The course proper extends over a period of two years, but must be preceded by a preliminary three years' course in the School of Science, or its equivalent. These first three years are essentially the same as the course in the Department of Civil Engineering, and the subjects required for admission are the same. They include the English branches; in mathematics, arithmetic entire, with the metric system, algebra, plane geometry; languages, either French or German grammar and translation. In the freshman year a great deal of attention is paid to mechanical and technical drawing. Throughout the entire course great stress is laid upon mathematics, and the work therein is very rigid. At the end of the junior year the regular student is prepared for and admitted without further examination to the Department of Electrical Engineering. The student then enters the electrical course proper, although during the first year some of the work is with the regular required senior course. It includes applied mechanics, theory of machines and prime motors, mechanism and machine drawing and strength of materials. Eight hours a week are given to the study of these subjects throughout the year, and elementary work is done in the physical laboratories during two days of the week. In the second year the theory of electrical measurements is studied, Fleming's "Alternate-Current Transformer" being the text-book employed. Advanced electrical measurements and the testing of the various machines form a part of the second-year course. Meetings are held once a week, in which the students present reports and discussions on the current electrical literature. In addition to the facilities afforded by the laboratories of the John C. Green School of Science, two buildings specially designed and constructed have been provided to meet the requirements of this course. The dynamo building is L-shaped, the boiler and engine occupying one wing of the L. It is constructed of rough ashlar brown stone with light sandstone trimmings, and makes a very pretty companion to the handsome Scientific School building. The dynamo room is 53 feet long, well lighted and ventilated. The floor is of artificial stone, flush with the heavy timbers which form the foundations, to which are bolted the bed plates of the machines. The engine belts to a countershaft at the ceiling, from which the dynamos take their power. Each belt pulley has a separate clutch, controlled by a long handle from the floor. A 60-horse Babcock and Wilcox boiler supplies steam to a 60-horse Ball tandem compound engine which furnishes power for the machines. The dynamos are of various types, including a Westinghouse alternate-current machine of 500 lights capacity, a Brush arc lighter of 18 lights capacity, an Edison of 200-light capacity, a Mather of 200, a Brush incandescent of 100, and an Eickemeyer of 50 lights; whilst a small Gramme machine charges four sets of accumulators. The dynamo room also contains a German silver rheostat, capable of absorbing 50-horse power. Some little distance from the dynamo is the magnetic observatory, which is built entirely without iron, brass and copper being used instead, even the motor used for stirring the water in the tanks in which the resistance coils are placed being constructed without iron cores.

MAGNETISM IN IRON AND OTHER METALS.*—XXVII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 373.*)

§ 103. Apparatus for Applying the Isthmus Method.—In applying the isthmus method it is desirable to be able to turn the bobbin round suddenly between the magnet poles, in order to determine the ballistic effect produced by reversal of its magnetism. An arrangement used by the writer for this purpose is shown in Figs. 73 and 74. Fig. 73 shows the electro-magnet as a

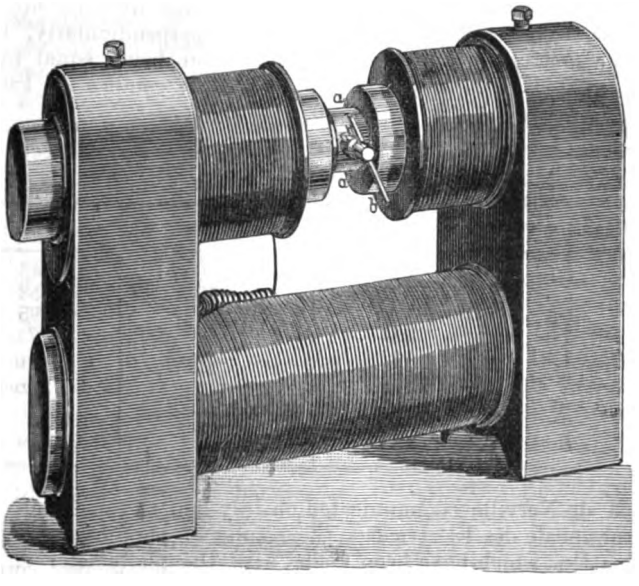

FIG. 73.—Electro-Magnet for the Isthmus Method.

whole, and Fig. 74 is a sectional sketch of the pole-pieces and bobbin and bobbin-holder. The poles, which are four inches in diameter, admit of having the distance between them adjusted,

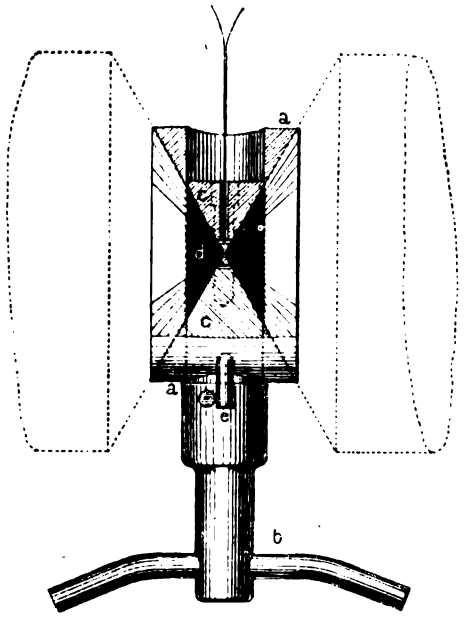

FIG. 74.—Section through bobbin and bobbin-holder.

and a brass piece *a a* is fitted between them, having hollow cones turned out of its ends, into which the conical pole-pieces fit exactly. This holds the pole-pieces at the proper distance apart. Through the brass piece, *a a*, a cylindrical hole is bored, extending through from side to side, and removing the points of the conical pole-pieces. Into this hole the bobbin-holder, *c c*, with the bobbin, *d*, is slipped from one side. The part which projects outside of *a* has a shoulder turned on it, which, when it is pressed home, brings the axis of the bobbin just into line with the axis of the pole-pieces. The bobbin-holder is of brass, and is made of two pieces, *c c*, between which the bobbin *d* is clutched, the pieces being fastened together by long screws put in from the end of the holder, which pass clear of the bobbin on each side of the neck. There is a little clearance round the neck to give room for the induction coils to be wound, and the leading wires from these pass out through a hole in the end of the holder. The bobbin *d* has its ends turned so that they virtually form part of the cylindrical surface of the holder, and it fits exactly into the cylindrical hole between the pole-piece ends. The handle *b* attached to the holder allows the bobbin to be suddenly reversed, and a stop is provided at *e* to make the movement exactly 180°. The electro-magnet of Fig. 73 is furnished with two pairs of conical pole-pieces, one pair sloped to give maximum concentrative power (§ 95) and the other pair to give maximum uniformity in the field (§ 97). For each pair a bobbin of the iron or other metal to be tested, is turned with the same slope, and for each pair there is a distance-piece and bobbin-holder to correspond.

§ 104. Experiments by Du Bois with Strong Fields. Optical Method.—The conclusions which were arrived at by means of the isthmus method, as to the existence of a finite limit to the intensity of magnetism, and as to the manner in which that limit is approached when strong magnetic forces are applied, have received independent confirmation from the later experiments by H. E. J. G. du Bois*, in which a novel and highly interesting method of measurement was introduced and used with excellent effect. The method is an optical one, based on Dr. Kerr's discovery,† that when plane polarised light is reflected by a magnet pole the plane of polarisation is turned, through an angle which depends on the intensity of the magnetisation. Before this fact could be turned to account for the purpose of measuring magnetism, it was necessary to know exactly what relation holds between the magnetism of the reflecting metal and the angle of rotation of the polarised ray. This question was made the subject of a preliminary investigation by Du Bois,‡ who answered it by examining the rotation of the ray when reflected from small surfaces, ground flat, and polished, on ellipsoids of iron, steel, nickel, and cobalt, the ellipsoids being magnetised by means of a surrounding coil. He found that the relation is of a very simple kind: the rotation of the polarised ray is proportional to the intensity of magnetism **I**, and may, therefore, be written equal to K **I** when K is a constant§ coefficient, to which Du Bois gave the name of Kerr's constant. He determined numerical values of K for iron, steel, nickel, and cobalt. Knowing these, it is, of course, possible to invert the process, and use the measurements of optical rotation to determine values of **I** in cases where they are not otherwise known.

This Du Bois has done in a way that will be readily understood by reference to Fig. 75 (taken from his second Paper). P_1 P_2 are the poles of a powerful electro-magnet, made conical, as in the isthmus method, for the purpose of concentrating magnetic force in the neighbourhood of the apex. Through one of them (P_2) a hole is bored to allow the polarised light to come to, and, after reflexion, to return from, the polished plate M, which is a small piece of the metal whose magnetism is to be examined, and is in contact with the magnet pole P_1. When the electro-magnet is excited, M is very strongly magnetised, and the value of **I** in it is measured by observing the angle of rotation of the polarised ray and dividing that by the known value of Kerr's constant, previously determined by experiments with a magnetised ellipsoid of the same material. J J is a steam jacket which was used to maintain the plate at a temperature approaching 100° C in some of the experiments.

We have said nothing yet about the manner of finding the magnetic force **H** acting on the plate M. It was not found directly; what was directly found was the induction **B**. When **I** and **B** are known, **H** may of course be deduced by means of

* All rights are reserved.

* Du Bois, *Phil. Mag.*, April, 1890, p. 293.

§ Constant, that is to say, for any one metal, and for any one wave-length of light. K differs much for light of different wave-lengths.

Digitized by Google

the equation $H = B - 4\pi I$. Now, in determining B in the plate, it is to be borne in mind that there is no discontinuity in lines of induction. The lines of induction here pass out of the plate normal to its surface, and B within the plate has the same value as the induction (or what is there the same thing, the magnetic force) in the air immediately in front of the plate. This fact was taken advantage of in determining B. It might have been measured ballistically by slipping out an induction coil laid on the face of M, or wound round the circumference of M; but the plan actually used by Du Bois was an optical one. A thin glass plate G, with a silvered back S, could be interposed in the path of the ray, immediately in front of the plate M—that is to say, at the place where a determination of the magnetic field was wanted. A plane polarised ray passing through a plate of glass in a magnetic field suffers rotation, as Faraday originally showed, and the amount of this rotation is proportional to the magnetic force and to the thickness of the plate. In the present case the ray passed twice through the glass plate. The plate was standardised by comparing the magneto-optic rotation in it with that in bisulphide of carbon, the value of which is well known. Thus, by means of two independent optical measurements, there were determined, first, the value of I in the strongly magnetised plate M of iron or other magnetic metal (by observing the rotation of a polarised ray reflected

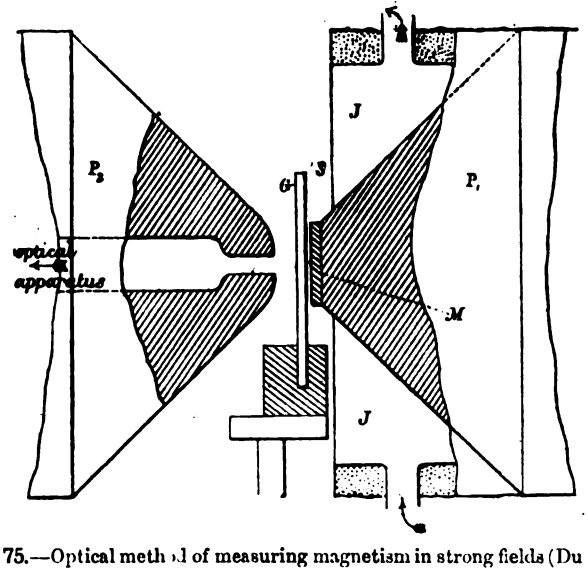

FIG. 75.—Optical method of measuring magnetism in strong fields (Du Bois).

by M), and, second, the value of B in the same plate, this last being equal to the magnetic force acting on the glass plate when the glass plate was put in front of the other, and being measured by observing the rotation of a polarised ray reflected from the silvered back of the glass.

(To be continued.)

MEASUREMENTS OF ILLUMINATION.

While the history of photometry dates from the work of Count Rumford at the commencement of this century, and has been carried to as great perfection as the power of comparing lights by the eye of a skilled observer will allow, no attempt appears to have been made until recently to measure illumination; that is to say, the degree of brilliance or luminosity in any locality produced by any arrangement of artificial lights or by daylight. A unit of illumination may be conveniently expressed in terms of a length and of a unit of light, being the illumination produced by unit light at unit distance. Mr. Preece pointed out at the beginning of 1884 that a carcel-metre is equivalent to a British standard candle at 12·7in.; and the name "lux" was suggested for it. The name has not been used, if for no other reason than that measurements of illumination have very seldom been made. M. de Nerville, director of the Central Laboratory of Electricity, has recently made a number of such observations in Paris. He has employed as a unit a bougie-metre, the bougie being a "*bougie décimale*," the tenth of a carcel burning 42 grammes of oil per hour. This is equivalent to a standard candle at 3·34ft. distance, which is a more convenient expression than one-tenth of a candle at 12·7in. The ·7in. cannot be neglected, since it amounts to a difference of about 12 per cent., a quantity which can be easily distinguished, and a greater difference than between yards and metres. The bougie-metre is a unit of very convenient magnitude. It is the same as the deci-lux of Mr. Preece, and is practically the illumination at the foot of an ordinary gas street-lamp, say 13 candles at 12ft.

The relations of the candle-power and the distance are, of course, very simple for light falling perpendicularly, the bougie-metre or deci-lux unit illumination being equal to 1 candle at 12·7 inches, or 1·058 foot, or n candles at 1·058 $\times \sqrt{n}$ feet, as shown in the following table:—

Bougie-metres.

Candle-power.	Feet.	Candle-power.	Feet.
0·1	1·058	8	9·45
0·5	2·37	10	10·58
0·8	3·0	20	14·95
1·0	3·34	50	23·7
1·5	4·1	100	33·4
2	4·73	200	47·3
3	5·8	500	74·8
4	6·69	1,000	105·8
5	7·48	2,000	149·5

M. de Nerville communicated on July 2nd to the Société Internationale des Électriciens the results of photometric determinations which have been made with the photometer of M. Mascart at the Opera, the Hippodrome, in the salons of the Hôtel Continental, at the Central Post Office and at the Halles Centrales at Paris. He refers to several general observations which he had communicated at a previous meeting on similar measurements made at the Exhibition. Tables are given showing the results obtained. They are expressed in bougies-metres. The screen of the photometer was 1m. 50 (4ft. 11in.) above the ground. Red and green glasses were used, and the readings of both are given.

At the Opera House, where the first series was taken, the auditorium has 450 Edison lamps of 10 candle-power, and 144 of 16 candle-power. Thirteen measurements were made in various parts of the house, with the screen of the photometer pointing in different directions, which are described in full in M. de Nerville's Paper. We find the average to be 10 bougies-metres for the red, and 9 for the green glass. Again, in the *grand foyer*, there were 524 ten-candle lamps. The average of seven measurements was 12 bougies-metres; or, omitting two sets taken under the arcade, 14 bougies-metres, the figures for the red and for the green being almost identical.

Two sets of measurements of the illumination of the Hippodrome were taken. There were 20 Jablochkoff candles of 4mm. in thick opal globes; 16 Gramme arcs of 25 amperes, in clear globes; 3 Gramme arcs of 45 amperes, and 8 Brockie-Pell of 12 amperes. Full details of each measurement are given, but, taking the average of six sets, we find that the red gave 44, and the green 70 bougies-metres respectively. The ratio of green to red for the glow lamps was unity in one case, and 9 to 10 in another; but for the arc lighting it is 7 to 4 or 1·75 to 1, showing the larger proportion of red and yellow rays from the glow lamps. The Petit Salle des Hommes of the Central Post Office is lit by 13 Cance lamps of 8 amperes. The red gives an average of 13, and the green 18 bougie-metres—a much larger proportion of red than in the larger arcs at the Hippodrome. One of the other rooms was lit with gas, with Cromartie burners, and gave an average of 9 with the red and 10 with the green, being a whiter light than that of the Edison lamp at the Opera House.

To compare artificial lights with daylight, several measurements were made at different times of the year, and in different states of the weather. The highest reading given is 1,110

Digitized by Google

bougies-metres with the green glass, and 3·26 with the red, giving a ratio of nearly 3 to 1. This was observed at four o'clock in the afternoon of May 1, 1890. The windows of the room in which the measurements were made were provided with white blinds, and in this case the sun was shining directly on them. On the same day a reading of 740 with the green, and 228 with the red glass was taken at 10:30 in the morning, the window not being directly facing the sun. The ratio here is 3·24 to 1. At five p.m. on the same day the ratio was 3·44, but the total illumination was about one-half of that of the morning observation. It may be assumed, then, that for pure white light, of which the sun is our standard, the ratio of the glasses in this particular photometer is about 3·5 to 1. The arc lighting at the Hippodrome, where the ratio was 1·75 to 1, therefore has a double proportion of red and yellow rays, compared with a pure white light, while the glow lamps and gas have 2·85 times the proper quantity of red light.

A reading was taken with the photometer turned towards the full moon, and the value was found to be about one-third of a bougie-metre. We have found it to be from one-seventh to one-fifth of this unit on clear nights, and are inclined to think that M. de Nerville's reading is rather high.

For interior lighting the production of illumination is almost invariably the only object of artificial lights, but out of doors it is otherwise. A lighthouse, for example, is not intended to illuminate a surface, but merely to be seen as a brilliant image. Other signal lights on railways and on carriages are intended chiefly to act as beacons, though a good carriage-lamp illuminates the road as well. Street lighting must be considered from both points of view. The mere illumination produced by the full moon, say one-fifth of a bougie-metre, would be sufficient for most purposes in the streets if this could be carried out uniformly by any artificial means, but street lamps act also as beacons. Even an arc lamp of 1,000 candle-power produces very little actual illumination at a distance of 150ft., say one-half of a bougie-metre on a surface turned to face towards it; but such a lamp would be very useful in a street as a beacon. The lighting of Cheapside, in 1884, by Brush lamps was of this character. The lamps, with the globes in their ordinary condition, gave about 400 to 500 candle-power. At the foot of each post, which was about 15ft. high, the illumination would have been 20 bougie-metres had there been no shadow. Midway between two lamps, the illumination on the ground was less than half a bougie-metre.

M. de Nerville does not give the averages of his measurements nor the ratios of the red to the green. The average of all the observations made in one locality does not give the true mean illumination of the place; but for the present purpose this is sufficient. He does not state how the readings with the red and the green glasses are to be dealt with; and it is generally acknowledged by the few who have taken any interest in the matter, that neither the sum nor the mean of the two is a measure of the total illumination.

In the large majority of cases, light is appreciated merely in so far as it causes the subjective effect of vision, and subjective effects on different individuals cannot readily be compared. One person may prefer an ample quantity of yellowish light, while another is equally satisfied with less, if it be of a whiter colour. The general public who need electric light are composed of both of these classes; and it is therefore useless to compare an illumination, say at the Paris Hippodrome, and to attempt to calculate the exact proportion between it and full sunlight, or ordinary daylight.

Electric and Thermal Conductivities.—In a recent number of the *Comptes Rendus* is a Paper "On the Ratio between the Electric and Thermal Conductivities of Metals," by A. Berget. The author has determined in absolute measure the electric conductivity k, and the thermal conductivity c, of copper, zinc, iron, tin, lead, antimony, mercury, and brass, at temperatures between 0deg. and 30deg. The ratio $k \div c$ varies from $1{\cdot}6 \times 10^3$ to $1{\cdot}8 \times 10^3$. The temperature co-efficient of the two conductivities is also different. Hence they can only be regarded as approximately proportional to one another.

ELECTRICAL FORGING AND CASE-HARDENING.

Two new developments of the electric welding process have been made, which indicate that there may be many other applications for working metal by electrical heating. In one of these, devised by Mr. Lemp, of the Thomson Welding Company, the ends of two bars are brought to a bright forging heat in a modified form of welding machine, but they are only in contact for a sufficient time and with the necessary pressure to allow the heat to be produced. They are separated, the current is shut off, and a die of any desired shape is introduced between them. They are then forcibly brought towards each other by a steam cylinder and piston, which presses the heated ends into the dies, and allows any required shape to be given to them. In this manner letter punches may be easily forged. Prof. Elihu Thomson has experimented also on the protection of the work during the operations of welding or forging from the oxidising action of the air. For this purpose a casing or chamber is constructed of sheet-iron in two parts hinged together and provided with insulating packing of mica or asbestos at points where the bars which are being heated are clasped. A current of hydrogen or nitrogen is passed through the chamber, thus displacing the air and preventing oxidation. A further development of this idea is the use of a hydro-carbon gas or vapour, by which "flashing" on a large scale is carried on, and a layer of carbon is deposited on the metal. When iron is used the carbon thus deposited carbonises the surface, which becomes steeled or case-hardened. From the brief account given in the *Electrical Engineer* of New York we cannot ascertain whether this method has passed beyond the experimental stage; and it appears to us doubtful whether the process could be carried out economically, since it must require time, and even if water-power or other cheap form of energy were used it would not pay to employ such expensive tools as welding machines and the powerful dynamos which are their necessary adjuncts for any prolonged work. Little is known of the diffusion of carbon in steel. The old process of cementation for making blister steel required some six or eight days for the carburation of three-quarter inch bars, and this was followed by ten days or a fortnight for cooling. It does not seem likely that the deposition of carbon in a nascent state would hasten the process. Of course the idea is only intended for superficial case-hardening. The new process can only be valuable if it will case-harden as deeply as the modified cementation carried out by makers of high-class machinery under the name of deep case-hardening.

---

(1) ON THE DISCHARGE OF ELECTRICITY THROUGH GASES; (2) ON THE FALL OF POTENTIAL.*

BY A. HEYDWEILLER.

Sir William Thomson first observed that the difference of potential necessary to cause the passage of an electric spark through a gas (air) between very close, smooth electrodes, is not proportional to the distance between them, but increases more slowly than this distance. Maxwell gives two explanatory notes on this point. The author wishes to corroborate that one which states that this may be due to a condensation of the air at the surface of the conductors, so as to produce better insulation, the two condensed strata being brought up to one another when the two electrodes are very close. A further question is as to what is the result in a non-homogeneous medium, as, for instance, between the surfaces of concentric cylinders, or two spheres external to one another. In the numerous experiments made on this point, no attention has hitherto been paid to the fact that the greatest and least values of the fall in potential at discharge are easily calculated from the size and distance of the electrodes and from the residual potential. This calculation shows also that the maximum tension is not nearly the same in all cases; but the mean (so called, absolute) values of the fall of potential taking place at discharge at the two electrodes in all cases with increasing distance, shows an analogy with that taking place in homogeneous fields. The limiting value of the fall of potential increases with increasing curvature of the electrodes.

The conclusions to which the author arrrives are:—

(1) It is possible to explain the peculiarity of fall of potential on a spark passing through air between smooth electrodes, on the sup-

* *Wiedm. Ann.*, Bd. 40, Heft. 7.

Digitized by Google

position of air being absorbed on the electrodes; but they must be larger than this layer of condensed air; further it decreases with increased curvature.

(2) The mean fall (*i.e.*, the arithmetical mean of the differences at both electrodes) is, in non-homogeneous, as in homogeneous, fields independent of the distance.

(3) The mean fall increases with increased curvature.

(4) From this mean fall, the maximum charge of a sphere in air may be calculated.

ON UNITS OF LIGHT AND BRIGHTNESS.*

BY PROF. DR. LEONHARD WEBER, BRESLAU.

Unit of superficial brightness: Important, but neglected. Suppose a luminous point be the source of light, the intensity of which is I, say, so many candles; then at the distance, d, the *quantity* of light which falls on a surface (at right angles to the rays of light), the superficial area of which is a, may be represented by $q = Ia/d^2$. But if we take into account the superficial brightness, or brilliancy, of the source of light, we must substitute for the term I, or intensity of the source of light, another term—namely, A·B., or the product of the *area* and the *brilliancy* of the source. Similarly, we may consider the brilliancy of illumination of the area illuminated; and this brilliancy (which we may represent by b) is found by dividing the quantity of light falling on the whole of that area by the area itself; that is, $b = q/a$. Thus we have three simple algebraic equations connecting the terms of our statements: these being (1) $q = Ia/d^2$; (2) $I = A \cdot B$; (3) $b = q/a$. To use these equations it will be necessary to fix our units of reckoning. Suppose we use, as the unit of bright or illuminated area, the square centimetre, and as the unit of distance the metre, then the second equation shows that the brilliancy B of an extended source of light is unity when it gives as much light per square centimetre (off its own area) as a luminous point of unit intensity would give at the same distance; and by combining equations (1) and (3) above we get the equation $b = I/d^2$, which means that the brightness of the illuminated surface is unity when it gets as much light from the source as it would have got from a unit source of light at one metre distance; this being the basis of measuring illumination, as distinguished from light, in "metre candles" (or "foot candles"). If we start from a unit of brilliancy instead of a unit of intensity we will arrive at corresponding values, but in every case we must distinguish between the actual intensity of a source of light, or quantity of light, falling on an illuminated area on the one hand, and the brilliancy of the source, or brilliancy of illumination, on the other. Now, the great difference between the platinum unit and the candle is that the latter is a standard of actual intensity only; while the former, since it defines the area of the source, is a standard both of intensity and of brilliancy. The amyl-acetate lamp gives a flame of about 2·27 sq. cm. in effective area; so that its actual lighting power being so-and-so in platinum units, its brilliancy will be less in the ratio of 2·27 to 1.

The range of brightness or brilliancy is extreme. A sheet of printed paper which we can just read is some thousand millionfold less bright an object than the sun at noonday; but the estimation of brightness is a matter of increasing importance, both with regard to the source of light and to illuminated objects; and the use of a standard of brightness will help to make clear our comparisons. From this point of view, the actual light from a platinum unit being about 20 times that of an amyl-acetate lamp-flame, and the area of that flame being 2·27 sq. cm., the brightness of the platinum may, if we please, be represented as 20 in amyl-acetate units, and that of the flame itself as 0·4. On the same basis the brightness of the sun is about 160,000, that of the sky 0·1 to 1, that of a printed paper which we can barely read 0·00006, and that of a barely visible surface 0·0000001.

A convenient subsidiary unit of comparison is the brightness of a piece of white paper at a distance of one metre from a unit source of light, and itself serving as a source of light, the brilliancy of which may be taken as a standard. But perfectly white matt surfaces cannot be obtained, and only approximate results could be reached in this way. It might also be of great advantage to use multiples of the unit of brightness, micro- and macro-units, as is now done with other units of measurement.

If the amyl-acetate lamp be adhered to, it might be used as a unit standard of brightness by taking only one sq. cm. of the flame; then other flames would be equally bright if one sq. cm. emitted the same quantity of light, and so on in proportion.

The following data, partly obtained in the laboratory here, and partly due to Dr. Michalke, Trebnitz, will illustrate this matter.

For red light (wave-length = 640 ten millionths of a centimetre) 1 pt. unit = 15·75 amyl-flames; for green light (w.-l. = 541) 1 pt. unit = 20·4 amyl-flames. Sperm-candle = 1·12 amyl-flame (Weber): 1·17 (Liebenthal). Violle makes the pt. unit equal in respect of white light to 18·5 sperm candles; whence it would be equal to 20·7 amyl-flames (Weber) or 21·6 (Liebenthal): [its *brightness* will therefore be to that of the amyl-acetate lamp flame in the ratio of 20·7 to 0·4, or 83 to 1].

* About.

A SUGGESTED ALTERNATOR.

We illustrate below a form of alternator, suggested more than three years ago by Mr. Mordey, which is of interest as showing an exceedingly simple form of machine, and as embodying the principle underlying a design from America, which is the latest "American novelty," and which we also illustrate this week.

The principle of the machine is shown by Fig. 1, which is a longitudinal section, and by Fig. 2, which is a partial end elevation.

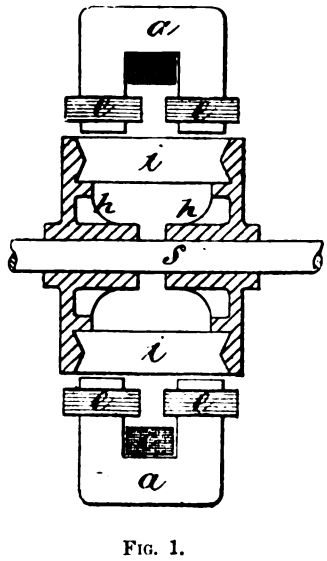

FIG. 1.

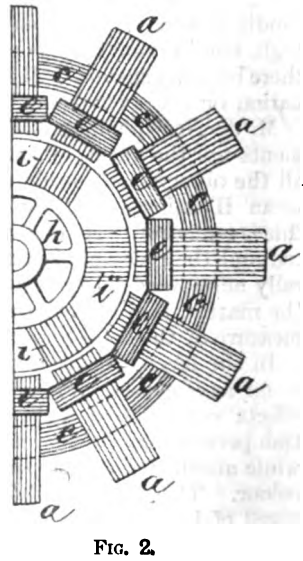

FIG. 2.

Diagram of alternating current dynamo, with rotating keeper, from Mr Mordey's Specification No. 8,262, 1887.

The machine is of the "rotating keeper" type. That is, a part of the magnetic circuit is rotated, giving rise to the generation of electromotive forces in conductors wound on other parts of the magnetic circuit.

The rotating parts are laminated iron blocks, $i\,i$, carried by means of the hubs, $h\,h$, on the shaft s. Coils $e\,e$, forming the stationary armature, are slipped over the ends of laminated U-pieces, $a\,a$, and between the legs of these U-pieces the stationary magnetising coil, $c\,c$, is wound. The action is very simple. As the "keepers" $i\,i$ are rotated the magnetisation of the U-pieces $a\,a$ rises and falls, thus setting up alternating E.M.F.s in the coils $e\,e$. It need scarcely be pointed out that the functions of the two windings may be reversed, $c\,c$ being made the armature, and $e\,e$ the field winding.

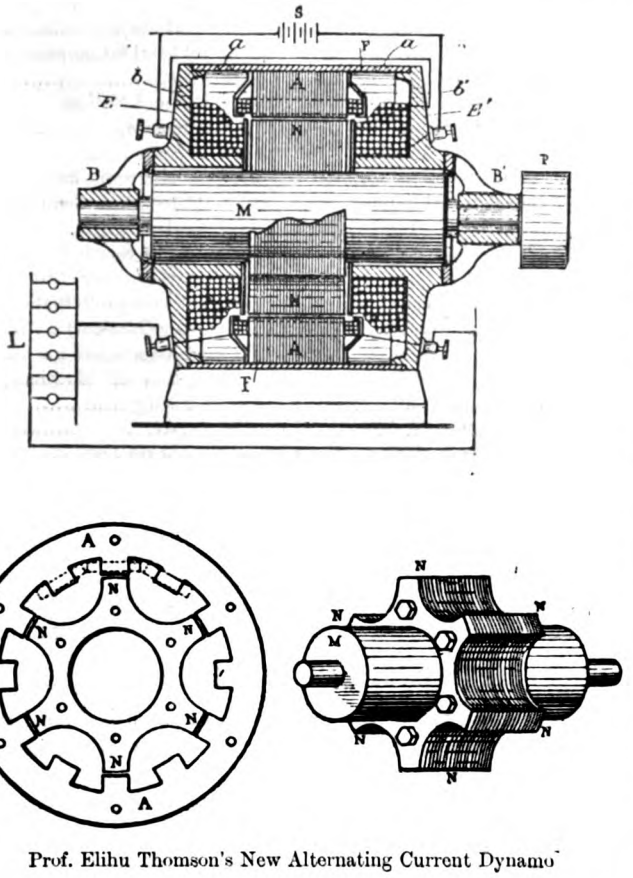
PROF. ELIHU THOMSON'S NEW ALTERNATING MACHINE.*

With the high speeds now generally employed in alternating current machines the moving coils are more or less liable to derangement, so that they are subject to both mechanical as well as electrical strain. In order to overcome this difficulty and to obtain a compact as well as efficient machine, Prof. Elihu Thomson has recently constructed an alternator in which all the coils are stationary, and so that no moving contacts whatever are necessary to conduct the current from machine to line. The machine is shown in section in the accompanying illustration, and consists of a stationary armature A, within which revolves the field-magnet.

The armature A is built up of a number of ring-shaped plates or sections of rings bolted together to form practically a compound laminated ring. It corresponds in a measure to a fixed laminated armature, and is supported in the interior of the outside casing.

The end plates E E′ are joined at their outer portions by the iron frame-work or casing F, consisting of a cylinder surrounding the machine. It is designed to connect the outer edges of the end plates E E′ magnetically with the stationary laminated ring A, surrounding the core M so as to embrace the centrally projecting



Prof. Elihu Thomson's New Alternating Current Dynamo

portions of the core M. To the inner side of the structure A, and upon projections extending radially inward, are applied the coils, the ring and coils thus resembling a multipolar ring or cylindrical-shaped magnet whose poles are on the inside.

The field-magnet coils are supported fixedly in the casing, and energise the multipolar field magnet M, all the poles of which are of like name, as shown at N N, &c. The core M is fixed to the shaft of the machine, and has the laminated pole-pieces keyed to it.

The ring structure A A has interior projections of double the number of the projecting poles N N N, carried by the ring core piece. On these projections are firmly secured the coils in which currents are to be induced, and which are connected to the line wires. The field-magnets, of course, require to be energised by a continuous current, which can be furnished by a separate exciting machine.

The action of the machine is as follows :—The moving field-poles N N N, &c., carried around on the revolution of the core-piece M, pass in front of the coils in which the currents are to be induced. The lines of magnetic force projecting from these pole-pieces cut across the wire on the coils transversely. The direction of the winding and the connection is such as to make the effects cumulative in the coils—that is, so that if a polar projection N passes over the centre of one coil to that of the next, shown in the lower figure, its lines are caused to cut the wire lying between those centres, half of which would belong to that coil the centre of which is being left by the travelling pole, and half to the coil toward the centre of which the travelling pole is moving.

These actions of induction repeatedly following one another will be accomplished without a reversal of magnetism in the core-piece, or even in the laminated ring structure supporting the coils in which the currents are induced ; but, on the contrary, the lines of force will simply be carried rapidly past wires, whose virtual direction of winding is opposite alternately, and this will generate impulses without the necessity of magnetic changes of polarity taking place in any of the core-pieces. Prof. Thomson is thus enabled to save a large portion of the loss due to magnetic changes or "hysteresis" in the iron of the machine, while still utilising the iron to the best advantage in the construction of the magnetic masses subject to the magnetising actions of the field coils. A strong magnetic field is also secured by the expenditure of a minimum of energy for sustaining the same ; and, besides this, none of the wire in the machine need revolve, thus dispensing altogether with rubbing surfaces or sliding contacts when the machine is used for the generation of alternating currents.

* From the *Electrical Engineer* of New York.

THE ROVELLO ELECTROLYTIC PROCESS FOR EXTRACTING COPPER.*

The cupriferous water obtained in the process of roasting copper pyrites in the manufacture of sulphuric acid is usually treated with iron filings, which precipitate the copper in the condition of an impure mass containing about 75 per cent. of copper, which it is necessary afterwards to compress, dry, melt, and refine. The object of M. Rovello's process is to electrolyse this cupriferous water in such a manner as to precipitate the copper in such a form as to render it immediately useful. His apparatus consists essentially of a large Daniell battery, the electro-negative elements of which are of sheet or cast-iron, instead of zinc, and are separated from the copper plates by porous partitions. The electro-motive force of an element of this kind (iron-copper) being about ·6 volts, a current of 200 amperes should be obtained with a battery of an internal resistance of ·003 ohms, capable of precipitating (at the rate of 1·19 grammes per ampere hour) 6 kilogrammes (13lbs.) of copper per hour. In order to lower the internal resistance to ·003 ohms, it is necessary to use electrodes with large surfaces and diaphragms of very low specific resistance. The electrolytic batteries are built up of a series of wooden frames separating the cathodes from the anodes by membranes of parchment. The anodes and cathodes are respectively fastened together by bars of copper. The frames and parchments are pierced by four holes, in which are inserted four tubes. Two of these tubes communicate with the even elements and a funnel, and the other two with the odd elements and a second funnel. The cupriferous liquid is poured in in a narrow stream and passes through into the cathode compartments, and the solution of sulphate of iron is poured into the anode compartments. These liquids escape separately by the overflow pipes. The weakened solution of sulphate of copper may afterwards be completely exhausted in a second apparatus. The operation is carried on without help from any source of electricity other than the baths themselves, which are short-circuited.

INVENTION AS A PROFESSION.

In these days, when each profession draws a jealous line of demarcation between itself and its neighbour, it may be interesting to inquire whether invention can be looked on as a legitimate profession. Can a man with a fair amount of ingenuity and originality expect to make a moderate income by devoting his talents to enlarging the sphere of mechanics, physics, or any of their subordinate branches? Can he after embarking on this line of life look forward to a reasonable amount of support from his fellow-labourers in keeping up the price of the wares they vend and insuring to the inventor a reasonable return for his labour?

There is a well-founded belief that the prospects of the inventor can never be quite so rosy as that of the man who succeeds in other professions. The invention doubtless may supply a long-felt want and may be of incalculable service to society; but the proceeds too often line the pockets, not of the needy inventor, but of the manufacturer who produces the article. "It is one thing," writes THACKERAY, "to write a novel, but quite another to get paid for it." So it is with inventions. It is when the preliminary work of inventing and patenting is over that the greater difficulties arise, and an opportunity is given of displaying a rarer genius in pushing the article in question and getting paid for it.

In treating of inventors as a class, however, we must carefully distinguish between discovery and invention. The

Digitized by Google

former term is generally applied to the pioneer who extends the boundaries of a science by bringing the observations of his predecessors under new laws, by introducing a new system of classification, by discovering a new substance or a new planet. Invention, on the other hand, seems more particularly to denote a new and ingenious mechanical arrangement or a more economical method of applying force. It is obvious that of these two divisions the latter is the most profitable; a great discovery, though of immense value to the intellectual world, may very possibly be of not the slightest immediate advantage to mankind, while the inventor through whose skill the cost of production has been reduced, appeals with greater force to the spirit of the practical man. Among the ancients, it is true, and more particularly among the Greeks, greater value was attached to discoveries of a purely intellectual character. It is related of THALES, who was the first person who inscribed a right-angled triangle in a circle, that on the performance of this feat he sacrificed a bull. We must not, however, be too ready to accept this as a sign of the wealth attained to by the men of science of that day, for it does not follow that because THALES performed the sacrifice the bull was necessarily his; and, if it was, it may have been the fruit of the more practical side of this versatile genius, who, besides being a mathematician, was a civil engineer. But to confine ourselves to inventions, we find that the most striking advances have often been made by practical men who by gradual improvements on the machine of which perhaps they have been in charge, have arrived at some completely novel method of performing the same process. Probably these very men would have been totally at a loss if asked to explain the process by which they travelled from the known to the unknown, having indeed made this instinctive leap in the dark and having been led to success by the fortunate co-operation of circumstances. This may account for the extraordinary manner in which the ancients advanced to a certain point but seemed unable to get any further. The classic philosophers knew in a vague way that sound spreads like waves, and PYTHAGORAS actually measured the relation between the length of a harp-string and its notes; but any real progress in the science of acoustics dates from yesterday. A rock crystal lens has been dug up at Nineveh, and the Arab astronomers had a considerable acquaintance with optics; yet ROGER BACON, who in the thirteenth century gave an intelligent account of their science, never seems to have conceived the idea of combining two lenses into a telescope; nor was it till the seventeenth century that GALILEO heard of one which had been constructed in Holland, and on which he afterwards improved. The loadstone seems to have been first used by the Chinese magicians, whom it assisted largely in determining the aspect of the heavens; while from the earliest times rubbing a bit of amber was a favourite experiment. Yet before the time of GILBERT no attempt had been made to treat the phenomena of electricity in a scientific spirit; and the further developments connected with the names of VOLTA, GALVANI, and OERSTED seem to us incredibly slow.

There can be little doubt that the rapidly increasing differentiation between theory and practice is a great hindrance to any great progress in the spirit of invention. True, the practical side is, on the whole, the most important, but it must be conducted in the right spirit; and even BACON, the great apostle of experience, confesses that the notions derived from "a few narrow and obscure experiments" are useless, since experience to be of any use must be conducted on a scale and in a manner only attainable by the man of science. "And therefore," he continues, "to those who daily converse in such experiments, and have thereby corrupted their fancy, this philosophy seems probable and certain, but to others incredible and vain; a notable example whereof we find in the chemists and their opinions, but now scarcely anywhere else, except in Gilbert's philosophy." It seems strange that BACON should have so little appreciated the merits of the founder of electrical science; but GILBERT probably annoyed him by his tendency—a tendency in which he has been frequently imitated—to reduce to electrical phenomena all the varied phases of the universe. But though it is undeniably true that most of the inventions which have facilitated production have been made by practical men connected with the industry in question, it is no less the fact that individuals are to be found who invent for the sake of inventing. Such men seem to have a surplus stock of mechanical ingenuity which they insist on utilising, either profitably or unprofitably. If they possess the requisite amount of scientific training their talents may be turned to good acount; but too often they go to swell the ranks of makers of rotatory engines which nobody wants, tramcar starters which nobody will use, and the mechanical fanatics of every description with which the Patent Office is only too familiar. The labour of these men, however, though too often unprofitable to themselves, is, when directed to useful channels, frequently of great service to the community. It is to them that we owe the thousand little mechanical contrivances that we use in everyday life; and to these men invention, being their one absorbing pursuit, is indeed a profession. In that somewhat disappointing work of BECKMANN on the "History of Inventions" we find an account of one HOHLFIELD, born in 1711, who seems to have been an inventor of this class. As he was an excellent workman and had invented several machines for shortening his labour, he found sufficient time to indulge his inclination for mechanics, and while pursuing his usual trade—that of a lacemaker—he made air-guns and clocks. He soon had opportunities of displaying his talents in the service of SULZER, and afterwards in that of a Prussian Minister. He showed the true spirit in turning his attention to other things than improvements in lacemaking. "Every machine that this singular man saw he altered and improved in the simplest manner. It is worthy of remark that he never bestowed study upon anything; but when he had once conceived an idea he immediately executed it. He comprehended in a moment whatever was proposed, and at the same time saw how it was to be accomplished. He could therefore tell in an instant whether a thing was practicable; if he thought it was not no persuasion or offer of money could induce him to attempt it." Such is the stuff of which the true inventor is made.

But if invention is a profession it still remains a question whether it is a profitable or, indeed, a noble one. To this question no very decisive answer can be given; so much depends on the invention, the inventor, and the circumstances. But it is worthy of note that to the account of HOHLFIELD, quoted above, our author naïvely adds these words: "He had a good heart." It is much to be feared that the combination of "a good heart" with the heaven-sent spark of genius necessary to the inventor is not likely to produce the article known as the "sound man of business;" and though ARISTOTLE was, we believe, the first person to remark that money-making was an art in itself, and only accidentally conjoined to other arts, we are afraid that the inventor must in all ages have painfully experienced the truth of the maxim. It is, after all, only the old story: the scientific pioneer and the man of genius have seldom, if ever, received an adequate return for their pains; but if, as is often the case, their best work is the result of an inspiration, they have, perhaps, little cause for complaint if their sole reward often takes the abstract form of fame.

REVIEWS.

"Electric Transmission of Energy." By GISBERT KAPP, C.E. Second edition. (London: Whittaker and Co., 2, White Hart-street.)

We are glad to notice a second edition of Mr. Kapp's very useful treatise on the electric transmission of energy. The author has been thus enabled to bring his book up to date. The changes in it comprise the addition of sections on the predetermination of the characteristics of dynamos, the reconstruction of the sections dealing with descriptions of dynamos, and the addition of further practical data. Descriptions of many now obsolete machines and of early experiments have been omitted. Beginning with a sketch of the capabilities of electric transmission of energy in utilising water-power, the first chapter opens with a few general principles, and in the course of this chapter a very clear explanation is given of the fundamental facts concerning an ideal simple system of electric motor and dynamo. Chapter II. deals with armature winding and calculations of the electromotive force determined by given dimensions and arrangements. Chapter III. brings us to discussions of the reversibility of dynamos, internal and external losses in conversion of energy, and efficiency of motors. Chapter IV. is largely occupied with a lucid description of the author's method of calculation for the predetermination of the characteristics of dynamos. Considering the method as a practical one, that is one fitted for the workshop or drawing office, it is undoubtedly a valuable method; but it is confessedly empirical, in the sense that arbitrary assumptions have to be made as to the nature of the magnetic leakage and the relation of magnetic resistance to density of induction for the magnetic circuit of the dynamo. Despite all that has been done to elucidate magnetic phenomena, the magnetic circuit still awaits its Ohm to do for it a service similar to that which this savant did for the electric one. But in the interval between complete ignorance and entire knowledge there is a region in which empirical methods of working have a useful field.

The structural development of dynamos and motors is an excellent instance of the fact that practice precedes theory in many, if not all, cases of practical invention; and that just sufficient grasp of the phenomena to present its fundamental facts to the mind, often affords the necessary foundation for invention. For this reason we do not want to be captious and split straws on the question whether the manner of presenting the facts, and of theorising on the basis of a magnetic analogue of Ohm's law, is really the best mode of treating the subject. Magnetic phenomena are more allied to electrostatic than to electro-kinetic facts in many ways; but it seems hardly advisable to raise a standard of revolt against a method which has become a very generally accepted one, unless something better can be put into its place. Chapter V. opens with an account of Prof. S. P. Thompson's useful methods of presenting graphically the laws of maximum activity and maximum efficiency of motors, and passes on to consider self-government of motors, and the employment of the compound dynamo as a motor. Chapter VI. deals with classification of systems of motors, self-regulation, distribution of power at constant pressure and at constant current, and contains an academical discussion of the effects of a leaky line and theoretical calculations of the efficiency of various arrangements. The next two chapters deal with the conducting circuit, and introduce Prof. Forbes' calculations for most economical sizes of conductors. The ninth chapter contains some very interesting comparisons of the relative cost of transmission of power by wire rope, electricity, water and air. The tenth and eleventh chapters are occupied with descriptions of dynamos and short histories of some early electric railways. The recent development of electric traction in America is treated very briefly. There are, perhaps, two reasons for this. In the early days of such work as this there is much that is of transient interest, but not so permanently settled in character as to make it desirable to place it on record in a text book, or it may be that the author considers that the methods of overhead supply there chiefly in vogue will not find any very extensive use in other countries. It is probable that in England at least electric traction is awaiting the perfection of an entirely efficient and satisfactory conduit system to make it more forward; or a combination of conduit and battery system which will enable cars to carry a reserve of energy for shunting purposes. The overhead wire systems are hardly more than pioneer methods which will in time give way to more solid constructions. But it can hardly be doubted by anyone who reviews the facts that electric traction is destined to become an enterprise of vast magnitude. When Mr. Kapp's excellent book has run into a third or fourth edition he may have to record some advances which will bring us within sensible distance of electric traction on railroads at speeds equal to or greater than those now usual. At present we are at the beginning of the work; but at all stages it will be of assistance to have the subject fully treated in a text-book; and this book of Mr. Kapp's places an excellent *résumé* of existing knowledge before the reader.

ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

(Continued from page 381.)

§ 10. **Transformers at Milan.**—Although the central station at Milan was designed originally on the lines of an Edison direct-current low-pressure station, it has been found essential to supplement the direct-current plant by an alternating transformer system to reach the outlying districts of the City. There are at the present time (1890) two combined engines and alternators by Ganz in the Milan central station, which machines are generally similar in arrangement, although slightly different in details to the steam dynamos at Leghorn. These alternators are of the 80 kilowatt size, driven direct by high-pressure engines at a speed of 250 revolutions, and generating a 40-ampere primary current at 2,000 volt pressure. There are no separate excitors, but the alternators take exciting current to the amount of 28 amperes or so at 110 volts from the Edison low-pressure mains. These machines, of which one is a reserve on the other, feed, with the usual Ganz regulating arrangements, into one single underground conductor of the Siemens concentric pattern, which runs from the station in the Via St. Radegonda to the Dalverme and Fossati Theatres, about 1¼ miles, or 1,800 metres from the station. In the Dalverme Theatre there is a bank of eleven transformers of the 7·5 kilowatt size, and in the Fossati Theatre two such transformers; these transformers feed between them about 1,300 incandescent lamps of 16 candle-power, 8 candle-power, and 10 candle-power. The cable carrying the primary current has a cross sectional area of 28 square millimetres in each member. The insulation after three years of working is very high, and is between 3,000 and 5,000 megohms per kilometre.

The transformers are of the latest pattern, as described in foregoing sections, and the arrangement for maintaining a constant potential at the supply end of the main is similar to that employed at Rome. The plant has been in perfectly satisfactory operation for three years, and will, no doubt, in time be greatly extended.

§ 11. **Other Transformer Stations by Ganz.**—The distribution of electrical energy by alternating-current transformers is making very considerable progress in Italy, under the system of Zipernowsky, Déri, and Bláthy. The list on next page gives the locality and approximate output (in 1890) of these stations in Italy. From this table it will be seen that at the date of writing (1890) the output of all the stations taken together, which work an alternating system, is about 4,000 horse-power, or some 3,220 kilowatts, and will in the immediate present be very greatly extended in consequence of the advantages offered by this system in utilising water power. Already, as is well-known, a very large alternating plant is being arranged at Tivoli, near Rome, which is to be operated by water power, and to furnish current for lighting purposes in the City of Rome.

At Marienbad there is a transformer station also operated by similar plant, which was inaugurated in May, 1889. Street

lighting is done by 36 alternate-current arc lamps, and by incandescence lamps, and about 1,800 slow lamps of 16 candle-power employed at private houses worked off a transformer system. The station is situated about a mile and a quarter from the centre of the town, and is a brick building, having an area of 600 square yards and divided into a boiler-house and engine-room. The dynamos are Ganz alternators of 50,000 watts output each. Four such dynamos are driven direct by Westinghouse engines made by Alley and Maclellan, in Glasgow. The excitors are driven by belts off the alternators. The alternators generate current at a pressure of 2,000 volts. The primary and secondary conductors are carried overhead on posts separated by about 35 yards, and the transformers are contained in weathertight receptacles on posts also. Three alternators are usually coupled together in parallel during the heavy time of load, and one machine held as a reserve. The dynamos work perfectly well in parallel, and are put on or off the circuits by the same arrangements as those described for the Leghorn central station.

There is a small water-power transformer station at Valreas and Dieulefit, which is interesting as an example of transmission of power. Valreas (Vaucluse) and Dieulefit (Drôme) are electrically lit by means of power taken from a fall of water at Béconne, three miles from Dieulefit and nine miles from Valreas. At Béconne there are a couple of horizontal turbines, which yield each about 50 horse-power at 180 turns per minute. Each turbine drives a Ganz alternator of 24 kilowatts output and an excitor of three kilowatts output. The regulation of the turbines is effected by an hydraulic regulator by Bouvier, and the regulation of the primary electro-motive force at the consumption end of the line is effected by the use of a mercury cup rheostat as before described.

The primary current is conveyed by a bare overhead silicon-bronze wire, of 3·2 millimetres diameter (No. 10, B.W.G.), and a resistance of 11·8 ohms to Dieulefit, and to Valreas by a similar wire of 6·6 millimetres in diameter (No. 3 B.W.G.) and 16·1 ohms resistance. The wires are carried on double-shed porcelain insulators. The transformers are held in iron cases carried on posts, and from them are distributed insulated secondary wires to the houses. The station, although very small, offers an interesting example of the conveyance and utilisation of water power by transformer plant.

In Paris, the Continental Edison Company carry out the lighting of the Palais de l'Élysée from their station situated about one mile and a quarter away, by means of Ganz alternators and transformers. Two alternators of 90 kilowatts and two of 24 kilowatts furnish current for 1,800 glow lamps in the Palace. The primary current is conveyed at a pressure of 2,000 volts by an underground concentric cable. The pressure is kept constant at the far end by the usual regulation of the exciting current, which is taken off from the direct-current machines in the same station. The four machines can be worked in parallel on to the single main, and the switchboard is arranged to permit this to be done.

(To be continued.)

THE EDINBURGH EXHIBITION.

The exhibit of the Electrical Engineering Corporation includes Statter and Brunton constant-current dynamo (Fig. 1) as supplied for driving tramways in the Via Flaminia at Rome. This machine is fitted with Statter and Brunton's patent automatic regulator, and maintains a constant current of 60 amperes with a maximum pressure of 750 volts at 750 revolutions. It will be seen from Fig. 1 that the machine has double circuit field-magnets, these are of forged "magnet" iron, and are machined all over; the pole-pieces are of cast iron, of ample section, and the joint between the wrought and cast iron is very carefully fitted, and being made on the end as well as the side of the slab, the area at joint is twice the sectional area of the slab.

The insulation resistance of these machines is very high, usually about ten megohms for the whole machine, and is obtained by the employment of mica. It is, therefore, a permanently high resistance, and does not depend upon paper soaked with shellac, which, though giving a very high insulation when dry, readily absorbs moisture, and so loses its insulating properties.

The armature is built of Swedish charcoal sheet, and is well ventilated; the winding is driven directly from the spindle, and

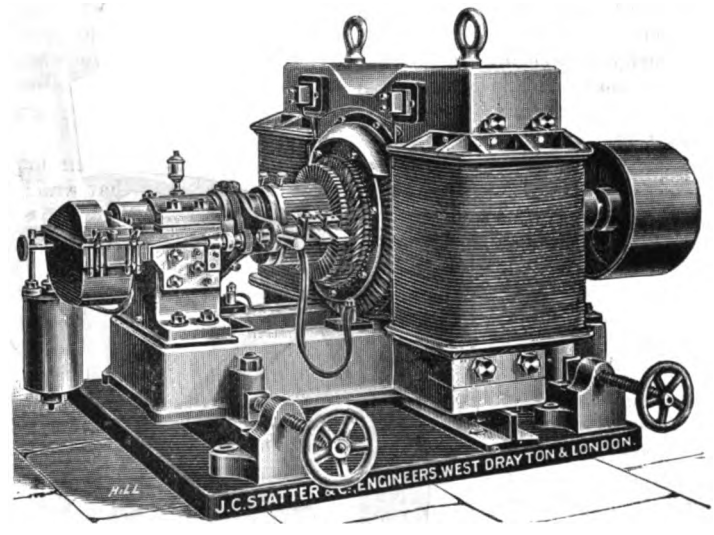

Fig. 1.

very firmly held in order to withstand the sudden alterations of load which take place in this machine when used for traction purposes.

In working, these machines run without heating, and the current is maintained at constant value with great accuracy. Sir Frederic Bramwell, in his report on the Northfleet tramways, states of this constant current generator:—"The dynamo is self-adjusting in its maintenance of a constant current. It is extremely interesting to watch the sensitiveness of this apparatus, and the manner in which it even forestalls the action of the engine-governor" (a sensitive high-speed governor). There are also two self-regulating series motors; these are of the same type as the generator shown in Fig. 1, and are provided with patent regulators, whereby the movement of the brushes is controlled by the action of a sensitive centrifugal governor. In all generators and motors made on this system the mechanism for regulating the current is enclosed in a small cast-iron oil-bath attached to the commutator end bearing, and neither the solenoid in the case of the generator, nor the centrifugal governor in the case of the motor, are required to exert any sensible amount of force, they merely determine the engagement of one or other of the driving pawls. It is in this manner that great sensitiveness is obtained.

The Statter-Brunton self-regulating gear has been described before in our columns, but it has been perfected in constructional details and made more compact. It can now be adjusted in a few moments, for a machine running in either direction all

Digitized by Google

working parts have been made amply strong, and as they work in oil there is practically no wear and tear.

The Corporation make these generators in nine standard sizes ranging from 3 kilowatts up to 80 kilowatts, and a corresponding series of constant-current motors ranging from 4½ horse-power up to 110 horse-power.

The constant-current generator is also employed for driving arc lights in series, and for this purpose standard sizes are made capable of maintaining from 6 arc lamps in the smallest size up to 120 in the largest, each of 2,000 candle-power.

This Corporation show their constant current motors applied to a hoist. The adaptability of their constant system is well illustrated by this application; the hoist shown is capable of lifting one ton at a speed of 100ft. per minute. The regulation patent; the governor is keyed directly on to the crank shaft, and is shown in Fig. 2. It acts directly on the cut-off of the valve, and while completely controlling the speed of the engine gives excellent results in point of economy in steam consumption. The engine is simple, since the available boiler pressure at the Exhibition is low. The Corporation make tandem compound engines of similar design with an improved piston valve, and would have preferred to exhibit one of these engines had the steam pressure supplied by the executive of the Exhibition been higher. Both simple and compound engines are made in eight standard sizes. A two horse-power nominal Atkinson gas engine combined with a 40-light compound-wound dynamo is also shown and used to drive some Statter arc lamps in parallel; the set forms a very compact

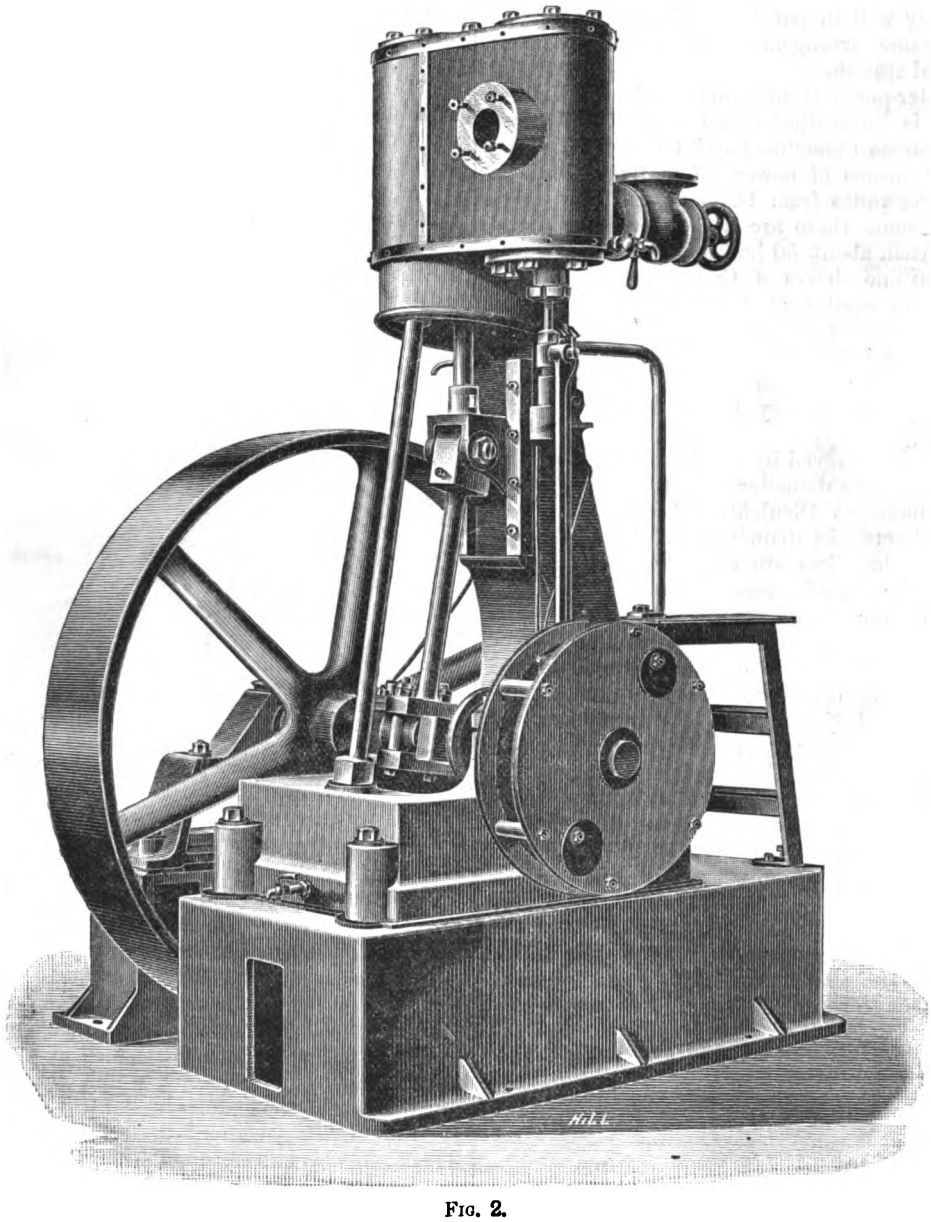

Fig. 2.

of the motor is by hand, and the motion of starting, stopping, and reversing is performed by the movement of a single lever, and is effected with great ease; the current is never switched off the machine during working, but after the hoist is done with the brushes are placed at right angles to the neutral point. The motor then comes to rest, and absorbs only the volts due to its resistance; it is then switched out of the circuit. Heavy sparking at the switches—inherent to all parallel systems of power distribution—is entirely avoided, and is one of the many advantages of the system. The hoist is wound for a constant current of 60 amperes, and absorbs 200 volts when fully loaded. The exhibit also includes a high-speed engine with automatic expansion governor (Turner-Hartnell's) plant for lighting private houses, and will be specially useful where space is limited.

This exhibit also includes a 20in. projector, made in accordance with the Admiralty specification. It is well finished in every detail, and furnished with signalling gear and with Statter and Brunton's patent diverging gear.

From their offices at the Exhibition the Corporation have carried out the lighting of the yacht "Katoomba," belonging to Kenneth M. Clark, Esq. Fig. 3 shows the set supplied for generating the current. The dynamo is compound wound, and gives 60 volts and 18 amperes at 1,400 revolutions; the engine is the smallest of the standard sizes made by the Corporation; the cylinder diameter is 3in. and the stroke 4in.,

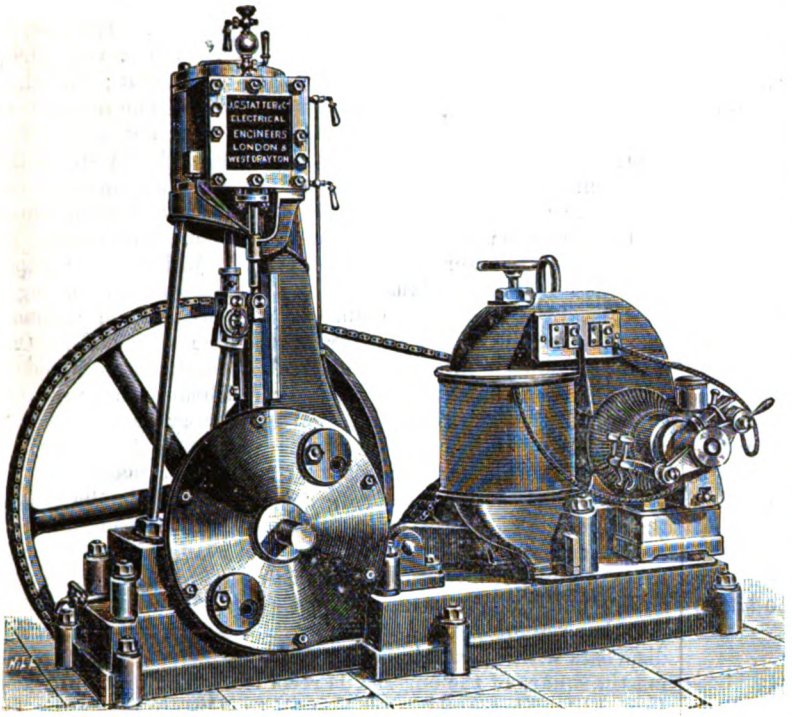

FIG. 3.

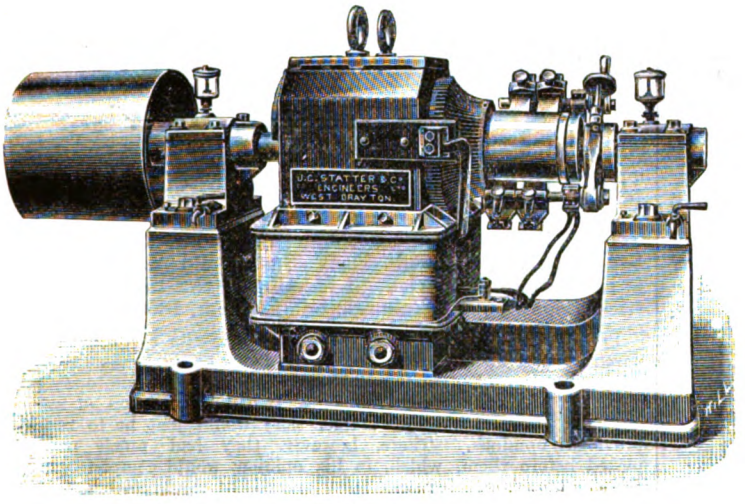

FIG. 4

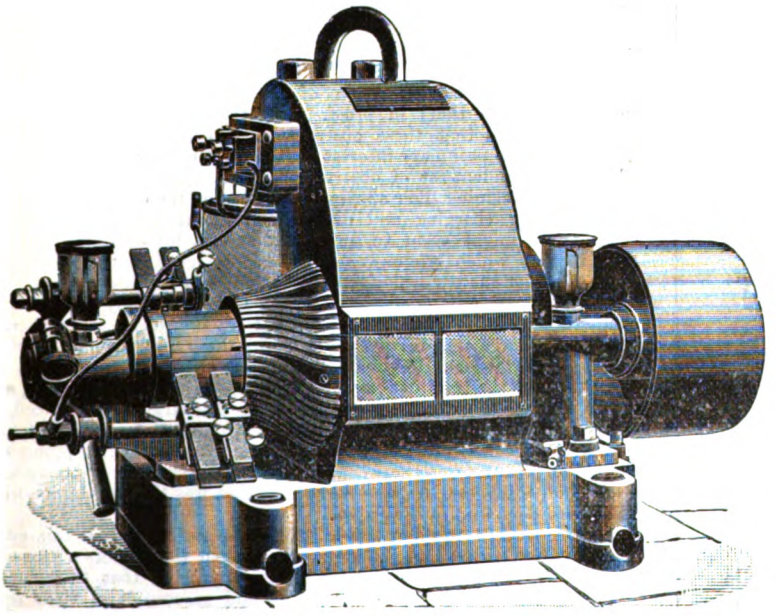

FIG. 5.

the whole set goes in a space of 2ft. by 3ft. 6in. by 3ft. high. Fig. 4 shows the standard type of dynamo manufactured by the Corporation for all sizes beyond 4 kilowatts, and Fig. 5 shows the type for all sizes up to 4 kilowatts. The dynamo of the larger type exhibited at the Corporation's stand has an output of 240 amperes at 120 volts, the field-magnets are made entirely of soft wrought-iron well annealed, and the armature of the softest Swedish charcoal iron. The Corporation make these machines for voltages up to 250 in eight standard sizes, ranging from six kilowatts up to 77 kilowatts, and they are described in their catalogue as type "B" dynamos. The smaller machines made to the design shown in Fig. 5 are in three standard sizes, and are described as type "A" dynamos. The armature of the "B" machines are of the drum type, and of the "A" machines cylinder type. Fig. 6 shows a geared motor supplied by the Corporation; it has a self-contained counter-shaft, and the power may be taken off it by means of belt, ropes, or pitch chains at a low speed.

The electric launches of the General Electric Power and Traction Company are running from 10:30 a.m. till 10:30 p.m.; each boat making journeys of an average of 35 miles a day. The accumulators are charged at night, the duration of the charging being from 6 to 7 hours. A charging current of from 25 to 30 amperes is used, at 100 to 125 volts. It is found that the four boats can be charged six times with a consumption of 4 tons of coal, which is supplied at 13s. per ton; £2s. 10s. per week is paid for the use of the engine. An average of 6,000 passengers is carried per week.

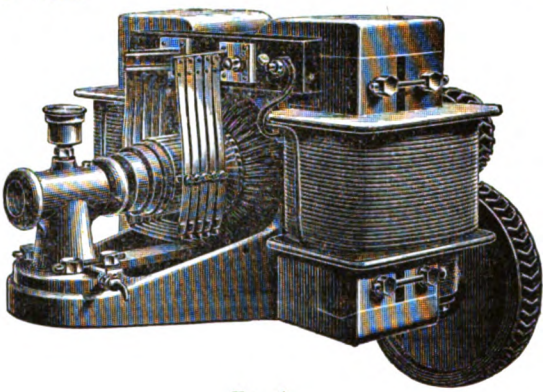

FIG. 6.

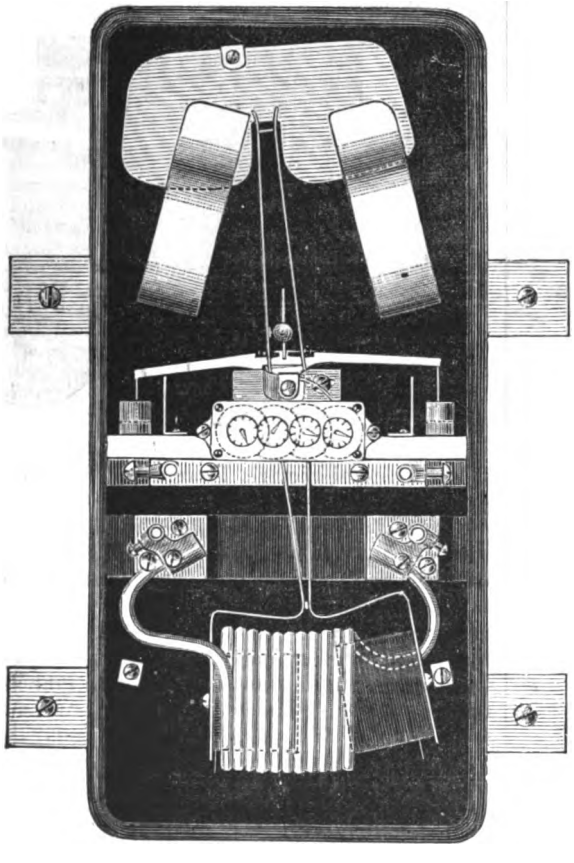
The General Electric Power and Traction Company also exhibit a good assortment of Immisch motors and dynamos, resistances, fittings for colliery work, lightning arresters, B type E.P.S. secondary batteries and propellers for their electric launches, as well as some of their motors coupled to mining machinery, which are shown in operation. This company's standard pattern of Immisch motors and dynamos is well known in mining, launch, and traction work. Different sizes are shown suitable for belt or chain driving, and in addition is exhibited a 25 horse-power Immisch motor, mining type, mounted on a suitable cast-iron trolley coupled to an Ingersoll rock drill, with a link chain for boring in any position in mines and quarries, &c. The motor is supplied with carbon contacts at right angles to the commutator, so that the motor will run in either direction without having to alter the brushes. At a speed of 1,200 per minute, with 150 volts and 16 amperes, the motor will give out 2·5 B horse-power; and when coupled to the above-mentioned drill is said to bore through rock at the rate of 5 inches per minute. The motor trolley has a pair of slide or belt tightening rails, with a worm

Digitized by Google

screw fitted to same and motor; hence the motor can be moved in a backward or forward motion as it is desired by actuating the worm handle. This firm have also a ½ horse-power motor driving a 36in. Blackman air propeller, as well as another 2·5 B horse-power motor, also mining type, driving a high-speed mine pump, with three rams, 4in. by 9in., throwing 3,280 gallons of water per minute through a head of 600ft. at the rate of 45 strokes per minute. They show a 4 horse-power motor of the horizontal pattern, similar to those used to propel the electric launches on the canal. There is also a 10 horse-power motor for a tram car, to carry 52 passengers, also of the horizontal type. It may be worth while to remark that all these motors are wound in series, the torque at the moment of starting being the maximum. For constant-current transmission the firm exhibit a series motor with an automatic arrangement for cutting out a certain number of layers of the field-magnet coils, thereby reducing the field magnetism. Amongst the electrical accessories are to be seen polished slate distributing switches, with double pole cut-outs, or fuses, for mine work; also colliery resistances with a very ingenious spark arrester for altering resistance in circuit. For the lighting of mines the company exhibit some fittings which are of a very strong and durable nature, the chief point being to externally protect the lamps from falling debris, &c.

PROF. ELIHU THOMSON'S ELECTRIC METER.

Prof. Thomson has invented an oscillating meter, the action of which depends upon the principle suggested by Ayrton and Perry, and put into a practical form by Siemens and by Hookham.



Prof. Elihu Thomson's Oscillating Meter.

It presents an advantage over these on account of the greater mechanical facilities which a pendulum offers for a slow movement, as compared with any arrangement for continuous rotatory movement. The Hookham meter, for example, while an excellent device for measuring a few amperes, requires great nicety of construction, and delicacy of pivoting to enable it to register one lamp. The motive force is then comparable to the friction, which is practically a constant quantity. The disc, or armature, then moves at its lowest speed, and a very slight increase of friction or other retardation will stop it; though it goes merrily enough with a fair current. The account of the new meter in the *Electrical World* does not give a full description of its action, but the illustration clearly shows the arrangement. A main coil carries the working current, and within it swing two shunt-coils, forming the bob of a pendulum. This is hung on knife edges, and works a counter-train, on whose dials the number of swings are recorded. The amplitude of the vibrations is limited by elastic stops. The swing is kept up by the alternate making and breaking of a shunt-current through one or other of the fine wire coils. One naturally objects to make and break of contacts in a meter, especially in shunt circuits; but Prof. Thomson has probably controlled the sparking by some satisfactory method. The upper part of the pendulum carries a sheet of copper, which passes between the poles of two permanent magnets. We presume that the weight of this nearly counterbalances that of the shunt coils, thus giving a slow period of vibration, and this is further controlled by dash-pots. The whole arrangement is, therefore, rather a reciprocating electric motor than an electric clock; and though it at first appears to be of the Aron class, it rather resembles the balance wheel meter of Prof. Boys, but dispenses with his admirable device by which the current, and not the square of the current, is recorded. The problem which Prof. Elihu Thomson has set himself to solve, in attempting to balance the various forces of electro-dynamic action, air friction, Foucault current retardation, elastic recoil, mechanical friction, and the considerable momentum of the moving parts, is no easy one, and we wish we had further details of the means he has adopted to place before our readers.

THE WORKING EFFICIENCY OF SECONDARY CELLS.

The following is the discussion on the Paper by Prof. Ayrton and Messrs. C. G. Lamb, E. W. Smith, and M. W. Woods, read at the Extraordinary General Meeting of the Institution of Electrical Engineers at Edinburgh, on July 16th, 1890:—

Prof. PERRY said he saw that nobody in the room was really prepared to enter upon a discussion of the Paper at the present moment. It was one of those Papers it was utterly impossible for one to say anything about on the spur of the moment. It had taken years of work; and anything they might say at that time would just be to repeat one's previous opinions. There, however, they had much new matter placed before them, which, in his opinion, would completely transform their old notions. He was sure everybody would feel astonished at the large working efficiency that had been obtained in cells when in working condition. They had learned from that Paper one very important lesson—that they must not take the cells blindly, as he himself had done some five or six years ago—and merely charge them up and discharge them without inquiring closely into their working effects. It was a most important thing to learn, that even in seven days for charging and discharging, the cells had not yet reached a state that they could tell what their efficiency was. He had a notion of that before, but there they had actual figures given them in proof. One thing of enormous importance was the fact that these observations had been made by people having actually no pecuniary interest in them; but they liked to have an absolutely independent set of observations. The ingenuity that had been shown in thus designing their apparatus for keeping the current absolutely constant during charging and discharging, might appear as a waste of energy. It might seem to some that such a lot of time should be devoted to work which is simply for the general good of the profession, and not at all for the particular good of the authors of these Papers. He was sure that Prof. Ayrton and his students had exceedingly little to gain in comparison with the enormous amount of work they had accomplished in their Paper. There was hardly anything in the Paper that was not of enormous importance. He should like to see somebody who could do what he thought the Institute ought to take steps to have accomplished, and that was, during the continuous charging or discharging of any cell, to distinguish between resistance and back-electromotive force. He found they even had been forced to go back on their own plan of stopping the current; but to distinguish between back-electromotive force and resistance was the chief thing, and he was sorry that that was the one thing which had not been gone into in the Paper.

Mr. KAPP said it was impossible to discuss a Paper like this on a moment's notice, seeing that the inquiry had taken the authors a year and a-half to work out their investigations. He suggested that they should not close the discussion that day, but should resume it at their next ordinary meeting, when everybody would have an opportunity of studying the Paper, and it would then receive the amount of attention which it deserved.

Lord BURY said his connection with secondary batteries was a practical one. He found that there was a great prejudice existing against secondary batteries, and a great belief that their efficiency was much less than it appeared to be. He was one of a few gentlemen who applied secondary batteries to electric traction. Whenever they got what they thought an improvement they were not content with trying that improvement, without trying it to the breaking strain. If in many instances cells delivered over to them really resisted their intense breaking power, then they found in the course of time—in the course of four or five years' experience—that they really could rely upon the cells to a much greater extent than was supposed by those outside. In the practical development of these cells there has been great improvement. Mr. Barbour Starkey had lately initiated an improvement in secondary cells, by which the rough usage to which they are subjected in the course of tramway traction might be much improved. As far as they had been able to test it, and they had done so very severely, they thought it would be a great and material improvement. They, as practical users of cells, had come to very much the same conclusion that, as he gathered from Prof. Perry and the reader of the Paper (Mr. Lamb), the gentlemen who had been making these investigations had arrived at—viz., that the efficiency of the cells themselves is much more reliable and higher than was at first supposed. He had no doubt that the test and investigations to which the secondary battery would now be subjected would still further prove that truth.

The CHAIRMAN said he quite agreed that they should have a full discussion on that important matter at a subsequent meeting; but they wished to take advantage of the present gathering to extract as much as they could from those present as to the discovery from the practical side of these cells.

Mr. BARBOUR STARKEY said he had only tried to overcome difficulties as he saw them arise and become almost intolerable. He had tried various experiments, but, generally speaking, it had not been work of a very severe character. The use of carbonate of soda in accumulators he had found of great value. When they had to stand for a long time, he was struck by the way that scaling of the heavy discharges took place. He had tried various experiments, one of which might seem very crude to electrical engineers. It was to put in a substance of great resistance—plaster of Paris—between the plates; and, to make it more porous, he tried various materials to mix with it. The first time he tried it was last year in Scotland, when he put into the cells a mixture of 2½ parts of fine sawdust to one part of plaster of Paris. That mixture he placed in the cells in a dry state, and added a little nitric acid and carbonate of soda. He was rather surprised, when he returned at the end of June, to find when he put on the switch that the lights went up as brightly as when he left in the autumn. He had at first thought that plaster of Paris would not be a good insulating material, but he now found that he had been mistaken.

Mr. FRASER, engineer to the Electric Traction Company, London, said that three years ago he had experimented in the variation of resistance in reference to current. They all knew the formula for obtaining the maximum work with the discharge of an accumulator, supposing that the resistance is of a given value. Taking the cell fully charged, its E.M.F. would be something between 2·1 and 2·2 volts. Take it at 2·15. If they differentiated the formula for the maximum work, that gave the current to be equal to E by 2 R. If it were the case, an accumulator whose electromotive force would be 2·15, its resistance ·C05, that was $\frac{5}{1000}$ of an ohm, should give out maximum work with 215 amperes, and potential difference =1,075; maximum work, however, corresponded to 300 amperes, and short-circuited, should give them a maximum current of discharge of 430 amperes, which it would be possible to obtain from such an accumulator. He had short-circuited the cell, and instead of getting 430 amperes as the maximum current, he got between 500 and 600, showing absolutely that the internal resistance of that accumulator, which with the ordinary working current to which they put it was ·005 ohm, or $\frac{5}{1000}$ ohm, must have fallen in an increase of current to half of the value; otherwise it would have been impossible for it to give out that current of between 500 and 600 amperes. Further, at that time he had tried in a practical way to discover how that resistance varied, and a very convenient form presented itself. The resistance of an accumulator varied in inverse proportion to the current which it gave out. Allusion had been made in the Paper to the difficulty of reading the potential difference of one element. That, of course, was exceedingly difficult; but he would suggest that instead of making the experiments with one or two cells, it should be made with 100 or 200. That would obviate that difficulty completely, and it would further give them the advantage of testing and comparing those cells between themselves; for if they had a large number of cells they would, he was afraid, very soon discover a want of uniformity in the construction of them; so great, indeed, that the one standard cell they might select would stand as no criterion of the other 99 cells that went to make up the 100. The rough treatment which accumulators had in heavy traction work, and the variation of current they had to give out, unless the cells were exceedingly well made indeed, and unless there was great uniformity when the cells were delivered, he was sorry to say that the plates did begin to scale sooner than they would like to see them; and they also began to buckle sooner, and they had to take out the plates. Mr. Barbour Starkey proposed that they should fill up the whole of the space between the plates inside the receptacle with a mixture of plaster of Paris and sawdust. Knowing the great trouble which was caused by the buckling of the plates—he was speaking now of having used 2,400 cells in the last year, and many thousands of cells on the Continent and in the United States and of having manufactured them also—he had been happy to give that arrangement a good trial. So he prepared four accumulators filled with a composition of two parts of plaster of Paris and one of fine sawdust. He was particularly careful to let it drop in gently, so as to have an even distribution of the mixture, and he was specially careful in filling it in that the receptacle should not be shaken to make it heavy at the bottom. He filled it all full, leaving forks in the cell until it was filled with the composition, and then he took out the forks one by one and filled the cavity left. He was at first anxious to know what effect the mixture would have upon the internal resistance and the weight of the cell. He was pleased to find that its effect upon the internal resistance was small. It did increase the resistance, but only to 5 or 6 per cent. The weight had also increased in a still smaller degree, somewhat; for one double cell with its liquid weighed 104lbs. made up in the ordinary way, and the same cell filled with plaster of Paris and sawdust, and absorbing very nearly the same amount of liquid, weighed 108lbs. He was so satisfied with the four cells that he had prepared a complete battery of 96 cells. That battery had been in use about three months, and the fault that he had to find with it was that its extra resistance for high currents—30, 35, 38, or 40 amperes—became serious. It also became a source of inconvenience with the other batteries. One battery out of 12 to have a little more resistance than the others. What, however, he hoped to see was this, and if it came out as he expected he would be well repaid for the trouble—he hoped to see that battery at the end of a year, after he had given it 360 or 365 charges. If it still did its work at the end of that period he would be very pleased to compliment Mr. Barbour Starkey.

After a few words from M. HOSPITALIER, Paris, and Mr. MASSEY,

Mr. FRASER asked Mr. Lambe if he had made any experiments to determine the curve of degrees of potential of an accumulator immediately after it had been disconnected from its charging dynamo? That he (Mr. Fraser) had done some years ago, and he found that it varied in the same way that gravity itself varied—that was, it fell rapidly, then less rapidly, still less rapidly, and gradually died away. In fact, the common gravitation formula, $V t - \frac{a t^2}{2}$, represented that curve. If they observed the fall during one period, it was sufficient to give them the value of the acceleration, and also the value of the initial velocity.

Mr. SWAN said that, seeing accumulators or secondary cells were at present attracting more attention for traction and lighting purposes, it would be interesting to have some careful scientific tests made in the laboratory, in which the conditions under which the cells themselves were used would be reproduced—he meant with respect to the shaking. The question of the working efficiency of the accumulators was not one that could be found out by a single cell. He was shown the other day the effect of a slight blow on two different kinds of plates. One of the old used cells was taken and knocked up against the wall, and he thought 25 or 30 per cent. of the plugs came out. Whatever the efficiency of an ordinary cell might be under ordinary circumstances, the efficiency after a shock of that kind must be 25 or 30 per cent. less. He had been told by one who had to do with traction that one of the greatest difficulties in actual traction was the danger of one car making a slight tilt or two cars accidentally knocking together.

The CHAIRMAN said he was bound to confess that at the present day there was no subject of greater importance to the electrical engineer than that of the proper performance of secondary batteries. They were coming into use more and more every day, not only for the comfort of those who had their houses lighted by electricity, but for those who travelled by railway trains and electric tramway cars. In every branch of electrical engineering the secondary cells were being used more and more every day. The great prejudice, and there was great prejudice, against the use of these secondary cells was due to the inherent opinion that a secondary battery was a very inefficient instrument; and although the few had long felt that a secondary battery was not quite so efficient, the majority would feel that the authors of the Paper had done a very great work indeed, and that they had established by unmistakable figures the truth that as a machine the secondary battery was not a very inefficient one. Again, it had an important bearing on the question of the distribution of electricity over large areas for lighting towns. The favourite system at present was to distribute currents over wide areas by alternating currents; but there were those who believed in the secondary cells, and who believed that in the future the secondary battery would knock out of the field the secondary generator. He was bound to say that there were certain districts and areas which could be as efficiently, if not more efficiently, lighted by batteries than by any other process. The great defect that had been developed in those systems of distribution by secondary batteries had been their very low efficiency, and that had been attributed to the inefficiency of the battery. But he had very great reason to think that the very low efficiency of these systems of distribution by secondary batteries was due, not to the system itself, but to the means adopted for charging and discharging the cells. There was one curious fallacy that was very widespread indeed, and that was this, that because in charging a secondary battery they worked up to 2·4 or 2·5 volts, and in discharging that battery they got down to about 2·2 or 2·1 volts, therefore they had at once a loss of efficiency of 25 per cent. in that battery. It was one of the most absurd fallacies ever indulged in, and it was shown by the tables in the Paper that it was theoretically impossible to get as much out of their battery as they put into it. Practical men had arrived at very much the same conclusions as the authors of the Paper, and it had always been a great satisfaction to him to find that practical and scientific men were agreed. His cells had been in his house now for six years, and he had never had a flickering of the light. That was entirely owing to the fact that they had been treated, as secondary cells should always be treated, with great care and discretion. Practice had introduced another test, which was of very great value, and one to which he would urge the greatest attention, and that was always to watch the performance of the electric current. Above all, they should never omit to measure the density of their liquid by means of a hydrometer. Mr. Barbour Starkey had referred to the fact that he had introduced soda into his cells. He was very much struck, on spending a few days with Mr. Barbour

Digitized by Google

Starkey at Bridgenorth, to see the beautiful condition his plates were brought to. He had assured him that it was entirely due to the application of soda. He (the Chairman) was so satisfied that there was something in this, that he organised a long series of experiments, extending over two years, to determine the proper proportions between soda and sulphuric acid; and the conclusion he came to was that, in all secondary cells, it took 45 pints of electrolyte, which was made up of 39 pints of water, 5 pints of sulphuric acid, and 1 pint of saturated solution of sulphate of soda. As to Mr. Fraser's remarks, he wished he had remembered that, in 1884, there was a Paper read before the Royal Society by himself, where he showed that the internal resistance of a secondary cell varied inversely with the current; and in a Paper read last year at the Society of Arts he gave that formula, and showed that as they increased the current so the resistance diminished. He would point out that this automatic apparatus should be of great practical utility. It reminded him of an invention brought before them some years ago by Mr. Edmunds. There they had the future success of secondary batteries for the distribution of currents for electric lighting. If they could by such an automatic apparatus as that, or by that of Mr. Edmunds, bring in a cell when it wanted a charge, and let it work its way out when it had got its charge, they would get rid of that waste of energy that was now so prominent and so marked, not a waste of energy in the battery itself, but a waste of energy in charging the cells.

Mr. E. W. SMITH having briefly replied on the discussion,

Mr. MURRAY MILLMAIN, Melbourne, requested the authors of the Papers to be prepared at the next meeting of the Institution to tell them the instruments they had used, and give a history of the cells upon which they had experimented, as he had before now been led astray by the results of investigations in consequence of the instruments used not being thoroughly explained.

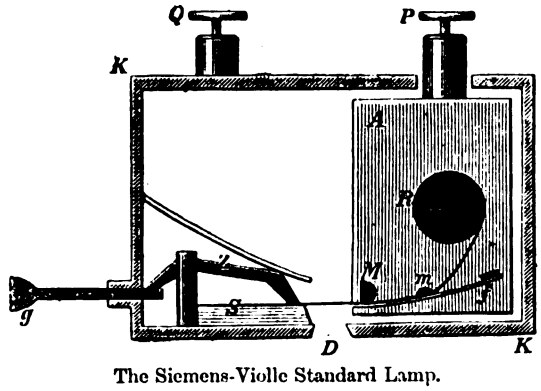
The Conference then adjourned for the day, it being understood that the Paper will be again discussed at the next ordinary meeting of the Institution in London, after members have had an opportunity of studying and mastering its contents.

ERRATA.—The authors have pointed out that a few errors appeared in their Paper as originally issued. In our last issue, in page 384, column 1 and last line but one, for "0·045 ohm" read "0·0045 ohm;" in the second column, line 5, for "0·11 ohm" read "0·011 ohm;" on page 385, column 1, for "0·038 ohm" read "0·0038 ohm;" and on line 5 for "0·09 ohm" read "0·009 ohm."

THE SIEMENS-VIOLLE STANDARD LAMP.*

BY DR. E. LIEBENTHAL.

The forms up to the present suggested for obtaining the unit of light passed by the Paris Congress have all of them many inconveniences, being both difficult to manage and most of them costly.



The Siemens-Violle Standard Lamp.

That illustrated in the accompanying figure has been specially designed to overcome these difficulties. A stand some 4in. high carries a box, K K, shown full size in the figure. On the bottom of the box is an insulated metal plate, A, on which is a small drum of platinum strip, R, a movable half cylinder, *m*, a larger fixed one, M, and a terminal, P. The strip passes under M and *m*, against which it is pressed by the spring *f*, and thence to the plate S, where it is clamped by the claw Z. The strip is now stretched by turning *m* backwards, and on passing a current through the instrument the platinum strip is melted, the light being observed through the aperture D. The handle *g* is now pressed, pushing S and Z forward, and at the same time lifting Z. On pulling *g* back, Z falls again, clipping the end of the platinum, and drawing on a fresh piece for the next reading.

The lamp does not absolutely fulfil the requirements of the Congress, as the source of light is platinum just melted, instead of melted platinum on the point of solidification; but, if it should be found necessary, a correction factor may be ascertained once for all. The cost is infinitesimal compared to that of the original standard, one gramme of platinum, costing about 2s. 6d., being sufficient for 50 readings. The metal is also obtained pure without difficulty, as there is, of course, no fouling due to the source of heat.

Preliminary trials with the lamp showed several small defects in the means of making contact on the right-hand side; these, however, were overcome by covering M with platinum, and abolishing *m* altogether, the strip being tightened by manipulating *g*. It was found also that more or less tension had but very slight effect on the results obtained. The current used varied from nine amperes to as much as double, due to variation in the gauge of platinum supplied. The strip used was about 5·5 mm. broad and ·011 mm. (·44 mils.) thick. A very large number of comparisons were made against the amylacetate standard, the current being slowly augmented, and the grease-pot carrier slid along the photometer bar as the light increased, the point at which the carrier stood when the coil fused being taken as the reading. The results obtained do not agree perfectly among themselves, the mean error in 180 readings being 2·9 per cent., whereas the same observer made two amylacetate lamps agree within 0·95 per cent. The errors are attributed both to variation of the platinum standard itself, and also to the fact that just before melting the light is considerably whiter than the amyl standard.

As the final result Dr. Liebenthal gives the value of the amylacetate standard as ·569 Congress unit.

Herr v. Siemens originally gave the figure as 0·7 legal unit, but thought that this was probably too high, owing to impurities in the platinum.

From previous experiments the value of the English standard candle had been found to be 1·169 that of the amylacetate lamp, which makes the legal value of the candle ·665 legal units. On the other hand, Herr Violle himself has made the value ·54, a difference of over 20 per cent.

In conclusion Dr. Liebenthal says that owing to the colour the platinum lamp is best suited for arc-light determinations, and recommends that the platinum should only be about ·2 to ·3 mils. thick.

INTERNATIONAL ELECTRICAL EXHIBITION AT FRANKFORT-ON-MAIN.

We are informed that boilers and engines with a capacity of about 2,200 horse-power have already been put down at this Exhibition. The dynamos are also in position. These will supply 1,000 arc lights and about 10,000 incandescents. It is expected that the lighting will far surpass anything that has hitherto been accomplished, and several novel and surprising effects will be shown. Besides showing the great advance which the electrical trades have made since the Vienna Exhibition, an endeavour will be made to arouse more public interest in this industry. We are therefore glad to learn that the Elektriziteits Maatschappij, Systeem de Khotinsky, Gelnhausen, besides accumulators and a collection of apparatus for installation work, will also during the time the Exhibition is open show the exceedingly interesting method by which incandescent lamps are manufactured. Visitors will thus be able to watch the details of the processes for making the carbon filaments and turning out the completed lamps.

With regard to the projected transmission of 175 horse-power from Lauffen-on-the-Neckar to the Exhibition, and the use of a potential of 30,000 volts for the purpose, Herr Popp writes to the *Finanz Herold* as follows:—

"I have for some time past experimented with currents at tensions up to 20,000 volts, and have arrived at the conclusion that the use of pressures of over 15,000 volts must always be attended by very heavy losses partly due to the leakage from one conductor to the other by way of the insulators, and partly by direct loss through the air. At 15,000 volts these losses in damp weather assume very important magnitudes. Leaving these, however, entirely out of the question, I find that the resistance of the conductor itself will occasion a fall of potential of over 4,000 volts, when a pressure of 15,000 volts is used, so that 15,000 volts at Lauffen will only give 11,000 volts available at Frankfort. Moreover, the difficulties of working out in an efficient manner so vast a project will certainly prove insuperable. I therefore regard it as absolutely incredible that the Berlin Allgemeine Elektricitäts Gesellschaft are seriously contemplating the undertaking. I am confirmed in this view by the demand which the Company makes for a copper conductor 350 km. long (outgoing and return) and 5 mm. diam. to be provided them. Such a conductor would, as you have remarked, cost quite 100,000 marks (£5,000), and there is also the possibility that the necessary poles could not be obtained. Even if some firm would furnish this free of cost by way of an exhibit, I am still convinced that the local authorities would refuse to allow the conductor to cross their land, either on the ground of danger or of interference with telephone and telegraph lines, and that the Allgemeine Elektricitäts Gesellschaft relied on something of this kind happening when they made their offer."

THE RESISTANCE OFFERED BY GASES IN A MAGNETIC FIELD.*

BY A. WITZ.

The first results which I had the honour to submit to the Academy elating to the action of magnetic fields on Geissler tubes required completion; indeed, after having studied the effects produced by a variation of the strength of the field, and also by a variation of the position of the tube with respect to the lines of force in that field, the effect produced by an alteration in the pressure of gas in the ube was still undetermined.

The following experiments have been made in a glass cylinder two centimetres in diameter, provided with taps and adapted either for compression or rarefication of the gas contained in it. The discharge oscillated between two electrodes provided with cones of aluminium. Under a pressure of 0·6 centimetre of mercury a purple discharge was obtained; with 230 centimetres a brilliant and powerful spark formed a path of fire between the two points. For intermediate pressures a spark and a discharge were observed simultaneously.

Now the effect of the magnetic field displays itself under these varying conditions in different ways. The discharge is diverted in accordance with the laws of electro-dynamics, the spark, however, is not; the effect then should be considerable for low pressures, whilst it should be eliminated at high pressures.

It was only a question of testing the exactness of these inferences. The following are the results obtained by experiment:—

Experiment.	Outside the field.		Within a field of 7,200 units.	
Pressure in cubic centimetres.	Current in millliamperes.	Difference of potential in volts.	Current in milliamperes.	Difference of potential in volts.
0·607	5·86	976	3·91	9,787
32·446	4·66	2,815	2·75	5,857
74·610	2·79	4,669	2·04	4,719
76·020	3·50	5,544	2·05	6,919
114·310	2·33	8,058	1·44	8,097
155·51	2·16	8,731	1·27	9,487
230·1	1·42	12,028	0·74	12,539

At the very low pressure of 0·6 centimetre the potential difference becomes 10 times larger, but there is no variation worth mentioning at 3 kilogrammes pressure. I think I am justified in concluding from this that the magnetic field only affects the electrical discharge. The influence of the magnetic field, which is so great in a Geissler tube, depends, therefore, on the constitution of this tube, and the state of rarefaction of the gas enclosed in it; and no effect is produced by it on gases in free space.

This gave a valuable clue to the analysis of the very complex phenomena observed in the Geissler tubes. The similarity of the effects produced by a magnet, and the approach of a metallic conductor (or even a finger) lead me to suggest a new explanation of these phenomena. That there is a striking similarity may be gathered from an example. A tube containing fluoxide of silicium gave me the following results:—

Outside the field.		Near a mass of iron.		Within a field of 11,570 units.	
Current in milliamperes.	Diff. of potential in volts.	Current in milliamperes.	Diff. of potential in volts.	Current.	Diff. of potential.
1·500	2,434	1·16	3,185	·99	5,730

It is true that these effects vary with the nature of the gas, the shape of the tube, the pressure, &c., but they can nearly always be verified on tubes in the sensitive condition. The phenomenon is sufficiently general to admit of the action of the magnet being ascribed to a change in the electric capacity of the Geissler tubes; these tubes, therefore, are really condensers, and their illumination is the result of an oscillatory discharge, similar to that of a Leyden jar, of which the period T is a function of the capacity C of the jar, and of the coefficient L of self-induction of the conductor, assuming the resistance to be very small, for $T=\pi\sqrt{CL}$. A change in the capacity C will vary the vibratory condition of the gas, and would be the origin of the differences observed in the luminous phenomena in a strong magnetic field.

* From *Comptes Rendus.*

THE DISTRIBUTION OF LIGHTS IN TEXTILE FACTORIES.*

The lighting for textile industries is here considered, first, because there exists none other which has need of so powerful lights, and secondly, because it has been thoroughly studied in all its details, and in consequence the type of factories is nearly the same in all countries, all of which may, therefore, be compared among themselves. The rooms are large and they contain a certain number of similar machines. The walls and ceilings are assumed to be white. For spinning, the minimum number of lamps should be one 12-ampere arc for 180 to 200 square metres (say 230 square yards, or 15 yards × 15). The maximum for a 9 or 10 ampere arc should be 80 to 100 square metres (say 110 square yards, or $10\frac{1}{2} \times 10\frac{1}{2}$ yards). These areas are for high rooms and for spinning unbleached or clear coloured yarn. For weaving the minimum is a 12-ampere arc for 120 square metres (133 square yards, or $11\frac{1}{2}$ yards square). For white unbleached or clear colours, a good light is given with a 10-ampere arc over an area of 75 to 80 square metres (93 square yards, say $9\frac{1}{2}$ yards square). But for black, and especially for dark colours, which must be distinguished thread by thread, some workers are not satisfied unless 10-ampere arcs are placed 7 metres (23 feet) from each other, that is 49 square metres (59 square yards) for each lamp. In general it is not advantageous to employ lamps of less than 8 or 9 amperes; 10 amperes gives a good light for industrial use. When the rooms are small, or the lighting is not evenly divided, 6 amperes may be used. For blacks and dark colours twice the amount of light must in general be used as for white or light goods, and even then the eye will be fatigued. In weaving light goods by glow lamps, a 10-candle and even an 8-candle lamp may be used for lighting two looms for unbleached stuff, and, on the other hand, for colours, two 16-candle lamps to a loom; or, if it is rather long, two 20-candle lamps are needed. That is exceptional, but it may be said that in most cases one 16-candle lamp will suffice for two looms. For arc lighting it is not a question of the number of looms, but the area which has to be lighted; it is, in fact, a general illumination. The room must be lighted and all that is in it, without troubling about any particular machine or part on which the worker is occupied. Arc lamps obviously cannot well be employed in small rooms. For outside work in courtyards and the railway goods yards an excellent effect is produced by lamps of 15 amperes, placed at 12 metres (40ft.) high, or, in case of need, lamps of 12 amperes at 10 metres (33ft.) high; but it is not advisable to use less than this. These figures have been arrived at by practical experience in Belgium and Germany, and it is because they have been departed from in lighting the streets of Paris that the illumination there tires the eyes without making things properly visible. There is an unnecessary number of lamps placed too low, and of too feeble an intensity; moreover, this arrangement is more expensive.

THE RESIDUAL CHARGE OF CONDENSERS.†

BY M. E. BOUTY.

M. Bouty used two methods for measuring the residual charge. In the first the condenser, after having been charged for three or four hours, was short-circuited for a time θ and insulated for a time t, after which the charge liberated in this time was measured. In the second method, which was less direct but more exact, the condenser A to be tested was joined up in series with a subsidiary condenser B, and with a battery of small resistance and constant electromotive force E. The auxiliary condenser B was short-circuited for a time θ, after which the condenser A was allowed to charge B, in cascade, for a time t. If x and y are respectively the potentials of the condensers A and B, and if the capacity of A is K, while that of B is unity,

(i.) . . . . . $x+y=E$

(ii.) . . . . . $d(Kx)=dy$;

or since E is constant we have

$$dx+dy=0$$
$$K\,dx+x\,dK=dy.$$

From these we obtain

$$dK=\frac{K+1}{E-y}\,dy;$$

or since y corresponds with the residual charge, and is very small compared with E,

(iii.) . . . . . $dK=\frac{K+1}{E}\,dy.$

* Abstract from a communication to *L'Électricien.*

† Extract from *Comptes Rendus.*

Digitized by Google

It is, then, sufficient to measure the charge $d\,y$, acquired by B in a short time, to deduce the increase, $d\,K$, of the capacity of A, and the increase, $E\,d\,K$, of the residual charge during the same time.

The times θ and t varied between 0·001 seconds and 4,000 seconds. For the longer intervals the commutations were made by hand, but for the other a torsions pendulum with mercury contacts was employed. A capillary electrometer was calibrated and used to measure the potentials.

The results of the experiments are briefly as follow :—

1. The residual charge liberated between the times θ and $\theta+t$ with the first method is identical with that absorbed by the same condenser in the second method between the same times θ and $\theta+t$.

2. The residual charge is proportional to the electromotive force of the battery used.

3. For a subdivided condenser the total residual charge is equal to the sum of the residual charges of the different parts, but these are not necessarily proportional to the capacities of the corresponding subdivisions.

4. For a Carpentier condenser, the residual charge R, liberated between the times θ and $\theta+t$, is given by the formula

$$R = A\left\{(t+\theta)^{0\cdot09} - \theta^{0\cdot09}\right\};$$

or between 0 and t,

$$R_t = A\,t^{0\cdot09},$$

where A is a constant.

5. The residual charge is small compared with the total charge. Taking the latter as unity, M. Bouty finds the following values for the residual charge of a Carpentier microfarad condenser :—

Value of t	·001	·01	·1	1	10	100	1000
„ „ R_t	·0180	·0222	·0273	·0336	·0412	·0507	·0624

These results are only exact if the battery employed has a small internal resistance. If a resistance is introduced into the circuit, or if a Latimer Clark cell of high resistance is used, the results are no longer precise. The batteries employed were very large, so as to have small resistance.

M. Bouty points out that errors arise in the determination of specific inductive capacity owing to uncertainties caused by residual absorption, and proposes to apply his results so as to obtain new and more accurate measurements. The investigation is also of value in determining the construction and mode of use of standards of capacity.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 1, 1890.

Fourth Avenue Railroad.—Additions to the rolling stock of the Fourth Avenue Railroad are now being made with rapidity. Four cars have been added within a short time, and others are being put on as fast as the batteries can be received from the factory. A few weeks will probably see a full electric service by accumulators on that line.

National Electric Light Association.—The meeting of this association at Cape May promises to be of considerable interest. A large number of electricians have expressed their intention of being present, and many interesting Papers are promised for the occasion. The last meeting, in Kansas City, was both well attended and important : but the present one, with its more available situation, will probably witness one of the largest gatherings of the Association yet recorded. At the same time the American Association for the Advancement of Science holds its meeting in Indianapolis ; and although the programme has not yet been definitely announced, it is understood that several electrical Papers will be read. In past years some very important electrical Papers have been read before that body ; although numerically the Association is not strong, it contains a large proportion of scientific men.

The Edison Company.—The re-organisation of the Edison Company is now formally announced. The change in management is a most complete and radical one, so that the organisation now is a unit—a great central office in New York, with branch district offices in various parts of the country. Previously it had been a rather loose combination of allied companies, and it is believed that the present change will result in greatly increased prosperity from the more business-like methods that will be followed. At the same time there are not a few grumblers among the electricians who are left out in the cold by the disorganisation of minor companies.

The Government Postal Telegraph Scheme.—Having been from time to time proposed, this is again before Congress for consideration. It seems to be improbable that anything will be done with the more or less vague plans which have been formed. We are hardly ready here for such a radical change, especially as most people who use the telegraph do not fancy the idea of a telegraph service which changes its organisation entirely at each change of administration. There is a pretty firmly rooted idea that a Government service, while it might be somewhat cheaper than the present one, would not be anywhere nearly as satisfactory ; and this popular prejudice is, in all probability, true.

Electric Tramways in Brooklyn.—There is a proposition now before the authorities to permit the use of the overhead trolley system for electric roads throughout the city of Brooklyn. The matter is being rather violently discussed in the newspapers, and it is not at all improbable that, after the successful experience of Boston with the overhead wires, Brooklyn may be induced to try it. It certainly would be a great victory for electric traction, if it is possible to break down the barriers of prejudice which have thus far interfered seriously with electrical progress in large cities. We have now something like 1,700 miles of electric roads in this country, and only a small portion of it is in the cities where rapid transit is most desirable. If the overhead system were successfully tried in Brooklyn—although we can hardly venture to hope it, in view of the legislative stupidity which marks the government of New York—it might be that at some future time we should have rapid transit on Manhattan Island.

CORRESPONDENCE.

THE EFFECT OF CIRCULAR MAGNETISATION ON THE RESISTANCE OF IRON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Will you kindly allow me to correct an error in my article on the above subject? The mode of conducting the experiment there described was, through a slip of memory, incorrectly stated. The time during which the battery key was kept down at each trial of the balance was not 10 seconds but only a fraction of a second. When I wrote the article I had not my Paper, "The Influence of Stress, &c.," *Phil. Trans.*, 1883, at hand, and I now find in it (p. 162) an account of the experiment, which, after having altered it in some unessential particulars, I send : "The sliding-piece was shifted until the double process of closing and *immediately* afterwards opening the battery circuit produced no sensible deflection. In this way the resistance ratio of the iron and platinum was approximately determined. The sliding-piece was then shifted a few divisions, first to one side of the apparent position of balance and afterwards an equal number of divisions to the other side, and the deflections produced by the double closing and opening process were noted. Thus, with three B A units in the battery circuit, the balancing point *seemed* to be 55 divisions to the right of the zero of the platinum silver wire ; on moving the sliding-piece first to 75 and afterwards to 35, deflections of 5 to the left of the galvanometer scale, and 6 to the right were respectively obtained. A left deflection indicated that the sliding-piece should be moved to the left in order to get a true balance, thus the true balancing point would be $35 + \frac{(6-\frac{1}{4})\,40}{11} = 56$ nearly." (The $\frac{1}{4}$ comes in because the impulsive effects on the galvanometer, arising from self-induction at the instants of closing and opening the circuit, evidently do not *quite* neutralise each other.)

In a similar manner the other readings recorded in the article were made.

Digitized by Google

Such a plan as the above is open to objection, and was only resorted to in sheer desperation of getting rid of thermal effects. It is true that the heating effect on the *resistance* of the iron was nearly the same as for the platinum, and that consequently the *real* resistance-ratio of the two metals would be but little affected; but this does not prevent error which arises from the fact that at the *junction* of the iron and platinum a *Peltier-effect* is produced by the passage of the current.

For currents of from 0·1 to 0·5 amperes I found it sufficient, after well coating them with shellac varnish, to immerse the platinum and iron wires in a large trough of water or oil, and in this case the current can be kept flowing long enough to allow the effects of self-induction to subside, and yet not to produce any very material error from heating.

I have spent a very considerable time over these experiments on circular magnetisation, and at the outset thought that I could detect a *true* increase of resistance from this cause; but the more the investigation progressed, the more did I become convinced that if there is a true alteration of resistance due to circular magnetisation at all, it is likely to prove too minute to be detected with any certainty.—Yours, &c.,

HERBERT TOMLINSON.

CONTINUOUS-CURRENT TRANSFORMER AT THE CHELSEA COMPANY'S WORKS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The account of the above, which appeared in your issue of the 1st inst., would lead the reader to suppose that the machine has only been subjected to "testing."

Will you, therefore, allow me to add that it has been in constant use for at least three months, during which time it has been used for augmenting the supply during the period of maximum demand.

Its load of 32 kilowatts in the secondary has always been easily rendered, and it has never given the slightest trouble, or required other attention than the usual oiling.

It is absolutely self regulating, maintaining a similar E.M.F. to that of the discharge circuit, whatever be the variation (if any) of the total output in watts.

Your description misstates the form of armature, which is of the "ring" form; the reason for the adoption of which being the convenience of winding and maintenance of insulation between the primary and the secondary coils.

There can be little doubt, however, that the "drum" type would give better efficiency; and probably future machines of this class will be so constructed.—Yours, &c.,

August 11, 1890. FRANK KING.

THE LIGHTING OF LONDON THEATRES BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read with considerable interest in your issue of August 1st, Mr. De Segundo's article about "The Lighting of London Theatres by Electricity;" and although I am somewhat late, I beg to ask you to rectify the figures relating to the cost of the installation at the Lyric Theatre. M. De Segundo writes:—"I may just mention, without comment, that this installation, as designed by M. Sechehaye, cost £19,000."

The real cost, including all the expensive fittings, £2,500 for storage batteries, and also one year's maintenance, does not exceed £8,000, which is not excessive if the extent of the installation (over 3,000 16-candle power lights and 12 arc lights) be taken into consideration.—Yours, &c.

EM. SECHEHAYE.

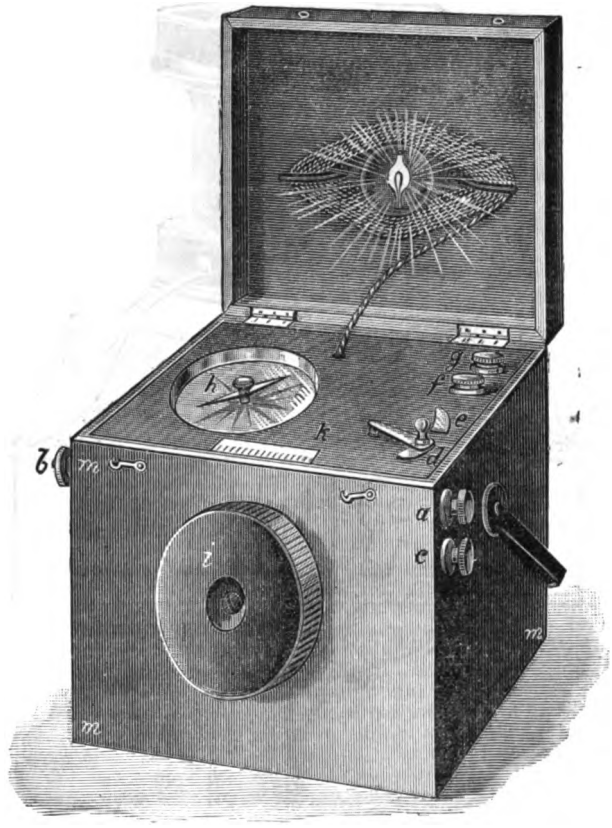
11, Queen's-terrace, St. John's Wood, N.W.,
August 13, 1890.

Annual Excursion.—The contract department of Messrs. Woodhouse and Rawson held their annual excursion on Saturday last, August 2nd, when a most enjoyable day was spent by a number of the *employés* at Brighton.

THE CENTRAL STATION COMPANION.

One of the chief difficulties which an electrical engineer has to contend with in central station work is the large number and inconvenience of instruments required for practical testing. This evil is growing daily, and any invention which tends to lessen it will be welcomed by the supply companies. A combination instrument called the "Central Station Companion" has just been invented by Mr. H. J. Dowsing and Mr. A. A. Day, the leading features of which are its compact form and simple arrangement, qualities which are greatly to be commended. Various combinations have been made, but the present form is the one which affords a great variety of uses in a remarkably small compass.

The "Central Station Companion," as usually made, is of the following dimensions, viz., 6in. by 8in. by 4in., and contains, 1, an ordinary detector or galvanometer; 2, a Wheatstone bridge to measure from ·05 to 50 ohms; 3, a standard ohm; 4, a variable resistance or rheostat; 5, a set of four small accumulators for giving a light when testing; 6, necessary switches, connections, contacts, &c. If required, a 10-ohm standard coil can be inserted to increase the readings tenfold. An essential feature of the "Central Station Companion" is its simplicity. Any workman can use it, and as there are no loose keys, complicated coils, or calculations to make, mistakes cannot occur.



(*a* and *b*) Bridge terminals for resistances (switch on *d*) (*b* and *c*) Detector terminals; (*d*) Contact for switch when using detector; (*e*) Contact for switch when using bridge; (*f*) Battery key for use with bridge or detector; (*g*) Galvanometer key for use with bridge; (*h*) Galvanometer; (*i*) Knob for adjusting bridge resistances; (*k*) Scale for reading resistance in ohms; (*l*) Incandescent lamp with connecting wires; (*m*) Case containing batteries, &c.

To use as a detector, the ends of the circuit must be connected to the two end terminals, and the key pressed, when the battery and galvanometer are put into circuit. To use as Wheatstone bridge, all that has to be done is to insert the resistance to be measured between two of the terminals and turn the knob in front (which inserts more or less resistance) while pressing keys until there is no deflection in the galvanometer. Then read the actual resistance from the scale. As above stated, there are no calculations required, and the resistance in ohms is read off direct. With a little adaptation the instrument can be used as a potentiometer, or for comparison of potentials by Poggendorff's method.

The incandescent lamp is a useful addition to the testing set and makes the instrument useful as a portable lamp, and the battery can readily be charged at any of the stations where low-tension continuous-currents are in use. If, however, it is preferred, a special form of Leclanché can be fitted, which will run a small lamp for a few minutes, giving ample time to make intermittent tests. It is an important point in connection with this testing apparatus that it can be made to measure higher or lower resistances as required for

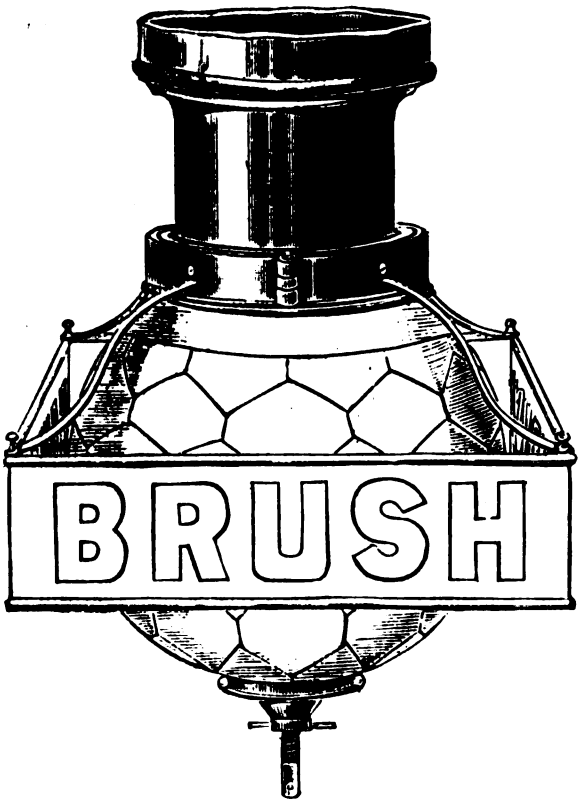
Digitized by Google

special purposes. The scales can be given a large range of reading at any desired point, so that accuracy may be assured. Perhaps the greatest arguments in favour of the "Companion," beyond its compactness and portability, is the low price at which it can be made. One of the ordinary size can be obtained at about half the cost of the cheapest form of Wheatstone bridge. The "Companion" is made by Messrs. Day and Co., of 60, Queen Victoria-street, who will give any further information required.

TRADE NOTES AND NOTICES.

THE DUBLIN SCIENCE AND ART BUILDINGS.—Four firms were invited to tender for lighting the new Science and Art buildings in Dublin by electricity—viz., Messrs. Siemens Brothers and Co., Messrs. Johnson and Phillips, Messrs. Edmundson and Co., and the Brush Company; and tenders were received from the three first named. Messrs. Edmundson's tender for £8,375, being the lowest, was accepted. The contract with them contains no stipulation as to giving a preference to any firm.

WADE'S PATENT ARC LAMP TABLETS.—We have received from the Birmingham Street Lamp Company an illustrated circular showing the various styles of their arc lamp tablets, one of which is shown in the accompanying figure. These are unquestionably very effective, and electric light contractors should send for particulars to the Company.



DISSOLUTION OF PARTNERSHIP.—The partnership heretofore existing between John Shaw, Thomas Connolly, and William Speakman Brown, trading as electrical engineers at the Newton Electrical Works, Newton Heath, Manchester, is dissolved. It will be remembered that the business of Messrs. Shaw and Connolly was recently acquired by the International Okonite Company (Limited).

REMOVAL NOTICE.—We are informed that Messrs. P. Walters and Co., telegraph engineers and contractors, have removed from 217, Latimer-road, Notting Hill, to 249 and 251, Kensal-road, London, W.

LUNDY CABLE COMPANY, LIMITED (IN LIQUIDATION).—Tenders are invited for the whole of the cable, land lines and plant belonging to the above Company, comprising about eight nautical miles of the main cable between Lundy and Hartland Point, three nautical miles of shore ends, three miles of spare cable, five miles of land line, a wrought-iron circular cable tank, paying-out and picking-up machinery, buoys, ropes, tackle, &c. Tenders are to be forwarded to the liquidator, Mr. Herbert J. Goss, F.C.A., 59, Wind-street, Swansea, on or before August 21st. Further particulars will be found in our advertising columns.

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED).—We have received an intimation that this Company have taken over the works and business of Messrs. King, Masterman, and Terry, iron and steel founders and boiler makers, of the Union Foundry, Kidsgrove, Staffs. These old-established engineering works are situated in the heart of the Staffordshire coal and iron district, and possess direct railway and canal communication with all parts of the kingdom. Messrs. Woodhouse and Rawson United (Limited) announce that they are now in a position to manufacture and supply complete plant for electric lighting stations, including engines, boilers, dynamos, accumulators, lamps, and all other accessories and fittings. Messrs. C. E. Masterman and S. H. Terry will undertake the management of the works. Messrs. Woodhouse and Rawson United (Limited) have also taken West End offices at 16, Great George-street, Westminster, which will be under the management of Mr. H. Sampson King.

MESSRS. DRAKE AND GORHAM.—We have received from this firm price lists of the Cardew Earthing Device and of the Cardew Patent Voltmeter.

LEGAL INTELLIGENCE.

Luther Hanson and Co. (Limited) v. Butler and Co.

This case was heard at the Yorkshire Summer Assizes. Mr. E. Tinda Atkinson, Q.C., and Mr. Waugh represented the plaintiff, the official liquidator of Messrs. Luther Hanson and Co. (Limited), electrical engineers, Halifax; and Mr. Lockwood, Q.C., and Mr. Kershaw were for the defendants, Messrs. James Butler and Co., engineers and tool-makers, Halifax.

The plaintiff sought to recover £115, the value of work done.

It appeared from the opening statement of Mr. ATKINSON, that in January, 1889, plaintiff entered into a contract with defendants to erect an electrical installation at their works. The plant was put down, but was a failure, as the lamps continually went out. They were what is known as the Luther arc lamps. The dynamos were worked by the engine working the rest of the machinery on the premises, and the plaintiff alleged that the failure of the lamps was owing to the irregularity with which the engine worked, and not to any defects in the lamps.

The defence was that the lamps were of faulty construction, and that they would not work satisfactorily, whatever the motive power was.

His LORDSHIP remarked that it was evident scientific questions would arise, and he did not feel disposed to deal with them.

Ultimately it was agreed that Mr. J. N. Shoolbred, London, consulting electrical engineer to the Bradford Corporation, &c., should be requested to examine the plant and report upon it; and his Lordship adjourned the hearing of the case until the receipt of the report.

WOODHOUSE AND RAWSON ELECTRIC SUPPLY COMPANY OF GREAT BRITAIN (LIMITED).—A petition for the winding up of this Company presented by G. H. Allfrey, was in the list on Saturday for hearing before Mr. Justice Stirling. It was ordered to stand over till next sittings, with leave to cross-examine in the meantime.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

July 21, 1890.

11,402. L. PFINGST. London. Improvements in couplings for electric railway vehicles.

July 22, 1890.

11,440. L. MANSFIELD. London. Electric railways.

11,465. M. W. DEWEY. London. Improvements relating to riveting by the aid of electricity.

11,466. T. M. FOOTE. London. An improved electro-magnetic friction clutch.

11,480. E. THOMSON. London. Improvements in dynamo-electric machines and electro-motors.

July 23, 1890.

11,490. F. H. ROYCE. Manchester. Improvements in armatures for electrical apparatus, such as dynamos, motors, and transformers.

11,495. A. HEALD. London. Improvements in appliances for use with gas lamps for producing light by incandescence.

11,499. A. E. WADLEY. Gloucester. Improvements in dynamo-electric machines.

11,520. J. P. BAYLY. London. An improved electric bath brush. (Robert Williams and Wilbur Shook, United States.)

July 24, 1890.

11,577. J. W. NEWALL. London. An improved method of propelling carriages by means of electric motors.

COMPANIES' MEETINGS & REPORTS.

Chili Telephone Company (Limited).

The first ordinary general meeting of this Company was held at Winchester House, Great Winchester-street, on Friday, the 8th inst., under the presidency of Mr. R. Raynsford Jackson.

The SECRETARY (Mr. Edmund Petley) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said the report dealt so fully with the business of the Company during the period over which the accounts extended, that it was quite unnecessary for him to occupy their time at any great length. They must have all, doubtless, read the prospectus of the Company, and they would have seen that the Directors had felt pretty confident that there would be no difficulty whatever in paying from the commencement a dividend at the rate of 6 per cent. As they would see by the report the dividend recommended amounted to only 2s. 6d. per share, which was equal to 5 per cent. Many of them would, no doubt, be inclined to ask the reason why it was to be 5 instead of 6 per cent. He would endeavour briefly to satisfy the anxieties of the shareholders upon this point. In the first place, when the prospectus was issued the rate of exchange was 26d. It had fallen to 24d., and the average rate of exchange during the eleven months over which the accounts extended was 25¼d. If the rate had continued at 26d. the earnings of the Company would have been between £900 and £1,000 more, and the dividend anticipated by the Directors would have been realised. There had been, moreover, another difficulty which the Board had had to contend against, and which had had the influence of preventing the General Manager in Chili from controlling the management of the Company until the middle of the last month of their financial year. It turned out that there was an unregistered body of shareholders in the West Coast Telephone Company, which was the vendor company, in Chili. Not having had their shares registered they were left in ignorance of the proceedings of the West Coast Company. They suddenly learned that the property in which they were interested had been sold, and they imagined that the sale price was over and above the liabilities of the Company, and that, therefore, they were entitled to receive a large sum. They were, however, altogether wrong in the view which they took of their position, because the West Coast Company's system having been sold upon condition that that Company should meet all its own liabilities, all that those shareholders were interested in was the amount remaining to the West Coast Company after those liabilities were met, and that was a small amount indeed. They, however, thought that they could protect their interests by preventing the legal registration of the transfer of the West Coast Company's telephonic enterprise to the Chili Telephone Company. The transfer had been completed, but the representatives of the dissentient shareholders asked for an injunction in the Chilian Courts to prevent the registration of the transfer until their claims were satisfied. The result was that the management of the Chili Telephone Company remained in the hands of the vendor Company until the middle of the last month of the year, when arrangements were made with the West Coast Company to appoint our general manager as their general manager, before which they had had little control, direct or indirect, over the affairs of the Company. Happily, their general manager had now a recognised position, which enabled him to look after the Company's affairs, to introduce economy, to improve the service, and otherwise develop and promote the interests of the Company. There had been an increase during the year of 33 per cent. in the number of subscribers, notwithstanding all the difficulties that the management had had to face, and he thought that they might anticipate a still larger increase in the current year, because not only had the adverse circumstances to which he had referred

Digitized by Google

been practically put on one side, but in addition they had purchased for £36,000 the only rival of the Company there was in Chili—the National Telephone Company of Chili. That Company was under the control principally of natives, who had considerable power and influence in Santiago and Valparaiso. They had been hostile to this Company, and they had co-operated with the dissentient shareholders so that the two together would have made it difficult for the Company to carry on its business satisfactorily. But owing to the purchase of the National Telephone Company of Chili, and to the fact that the dissentient shareholders had thereby been weakened and might speedily be settled with, he thought he might hold out to the shareholders the assured prospect that the Company would realise all the anticipations indulged in by the Board, and that they might congratulate themselves on the possession of a property of great intrinsic value. He concluded by moving—

"*That the report of the Directors and statement of accounts to the 31st March, 1890, now presented to this meeting, be approved and adopted.*"

Mr. THOMAS GREENWOOD seconded the motion, which was agreed to unanimously without discussion.

The CHAIRMAN next moved—

"*That a dividend of 2s. 6d. per share, as recommended by the Directors, be and is hereby declared, and that the same be payable at the Company's bankers on and after the 9th inst., free of income-tax.*"

The Hon. F. ERNEST ALLSOPP seconded the motion, which was agreed to *nem. con.*

The CHAIRMAN then proposed the re-election of Mr. Thomas Greenwood to his seat at the Board, and said that owing to the confidence of the other Directors and of the vendor in that gentleman, they had entrusted him with carrying out delicate negotiations, which he had managed with great tact, skill, and success.

Mr. VENABLES seconded the motion, which was carried unanimously.

Mr. GREENWOOD having acknowledged his re-election,

The CHAIRMAN proposed, and Mr. H. W. BARBER seconded, the re-election of the Hon. F. Ernest Allsopp to his seat at the Board, which was also agreed to *nem. con.*

On the motion of Mr. E. E. VENABLES, seconded by Mr. H. W. BARBER, Mr. Thomas A. Welton was reappointed auditor.

On the motion of Mr. ALEXANDER HENDERSON, seconded by Mr. WHITTET, a vote of thanks was accorded to the Chairman and Directors.

The resolution having been carried unanimously,

The CHAIRMAN acknowledged the compliment, and the proceedings terminated.

City and South London Railway Company (Limited).

The 12th ordinary general meeting of the proprietors in this Company was held at Winchester House, Old Broad-street, on the 12th inst., under the presidency of Mr. Charles Grey Mott.

The SECRETARY (Mr. H. H. M. Smith) having read the notice convening the meeting,

The CHAIRMAN proposed the adoption of the report and accounts. He reminded them that at the last meeting one of the tunnels was in an incomplete state. They were then, however, steadily driving it through the stratum of wet gravel at Stockwell; and he was happy to say that this tunnel was now completed, and no mishap had occurred. The whole of the tunnels were now finished, and he thought they might accord their best thanks to the engineers and contractors for the successful way in which they had carried out an exceptionally difficult work. He believed there was hardly on record anywhere so great a length of tunnel where there had been so little loss of life or accidents connected with it as had happened in their own case. He was glad to say that the completion of the tunnels had been followed by the completion of the permanent way, the rails being all laid. The electric main cable for conducting the electricity was also laid through both tunnels, and the service conductor which conducted the electricity to the locomotives was also laid through both tunnels. The two lifts had been a much longer period in being completed than they anticipated, or that Sir William Armstrong's firm had given them to understand would be taken. This had caused some delay in the completion of the work, because until the lifts were finished they could not proceed with many of the works connected with the stations and bridges. He was glad to say that the lifts were now making very satisfactory progress, and he hoped that it would not be long before they would see the works finally executed. The stations below were all practically finished, and above they were very nearly so. They had hoped to light the stations with electricity taken from the ordinary conductors from the supply power; but it was found that there were certain fluctuations of the light in taking power in this way, and also that a considerable amount of power was consumed which they were very unwilling for a moment to take from the propelling power which they wanted, and which after all was a most important question. For the moment, therefore, they had decided to light the stations with gas, but there was no doubt that ultimately they would be lighted with electricity. The signalling arrangements throughout the whole of the tunnels were approaching completion. At the depôt there were three hydraulic engines—that was, engines for compressing the water which drove and worked the lifts. Those engines were completed, and everything was in good order. There were three vertical engines of great power for driving the dynamos to produce the electric current. One of the engines had been working with one dynamo very satisfactorily indeed, and it answered all their expectations. A second vertical engine and dynamo were also ready, and would, he believed, be working for the first time that day. The third vertical engine, which was held as a reserve power, was very nearly completed. The engine and carriage sheds had been roofed in He was sorry the line was not open yet, as he had hoped. An engine and stock had run the whole length of the line with electrical power at a speed greater than was required for the service of the line. They had no reason to doubt now that the railway would be opened in a very short time. They were now busy engaging and arranging for the staff for working the line. Of course being, perfectly new to the work, it would be necessary that they should have some time in order to get acquainted with their duties; and, therefore, it would be necessary that the line should be run for a short time before it was open to the public, so that they might have no breakdown afterwards, and that everything might be in perfect order. They were taking every precaution to secure this object. He hoped that at the end of next month they would be able to open the line, but they must take it from him that that was his hope; for, after all their disappointments, he was very loth to predict. They could, however, judge for themselves from the particulars he had given that they were not very far off the opening now. The Bill to which they gave their assent for the extension of the line to Clapham had received the royal assent, and the name of the Company had been changed to its present title—the City and South London Railway Company. They proposed at a special meeting that day to create in the ordinary way, as most railway companies did, the capital authorised under that Act, but they had no intention of immediately going on with the extension to Clapham until they saw the line in working order. The Bill for authorising the Central London Railway Company, to which he alluded at the last meeting, and in which it was proposed to make a junction with this Company, and which would have been practically unworkable with their line altogether, had been thrown out by the House of Lords after a long inquiry. He was inclined to think that this was not an unwise proceeding on the part of the House of Lords. The Bill was not conceived on the lines of this Company or on lines which would have made it a profitable undertaking to its shareholders. It might and probably would be re-introduced in a better form, and if they could arrange to work with it they would be very glad to do so. There were certain points as to which they would have to get the shareholders' assent, and which would give them more control of the City traffic than they had at present, and at

comparatively small cost to their own line. Up to the present time they had spent some £666,000, but they had some valuable land as an asset against that amount. They had kept practically very close to their original estimates as to the cost of the line, and it was upon that cost that the future earnings and the future dividends upon the City underground railways must depend. The capital cost of any underground line in London must be kept within definite limits. The Metropolitan and District companies had an enormous traffic, and they saw what a very poor return those companies gave to their shareholders, notwithstanding that they had magnificent traffics. This was a warning which should never be forgotten by the shareholders, and in any extension they must recognise the fact that the cost of the line must be kept within certain known and defined limits if there was to be a proper return for their money.

Mr. SAMPSON HANBURY seconded the resolution, which was at once unanimously adopted.

On the motion of the CHAIRMAN, seconded by Mr. HANBURY, a resolution was passed, authorising the conversion of the existing share capital of the Company into Consolidated Stock.

The CHAIRMAN said that they did not propose to act upon this resolution at once, as it would be better that the share capital should be more completely issued at first. It would, however, be more convenient hereafter to carry out the conversion.

Resolutions were afterwards passed, creating, under the City and South London Railway Act, 1890, 20,000 new ordinary shares of £10 each, and authorising the Directors to raise by borrowing the sum of £50,000, and for that purpose to create and issue Mortgage Debentures or Debenture Stock.

On the motion of Mr. S. G. SHEPPARD, seconded by Mr. LOVELL, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN having briefly responded, the proceedings terminated.

Liverpool Overhead Railway Company (Limited).

The fourth half-yearly meeting of the shareholders of this Company was held on Tuesday in Liverpool; Sir Wm. B. Forwood presided.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, desired to explain in a few words the position of the undertaking. The works were not actually commenced till October last, and he regretted to say that the progress made was not so rapid as the contractors had led them to expect. This did not arise out of any difficulty in the construction of the overhead railway itself, that being a very simple matter indeed; but it arose from the automatic machinery which the contractors employed with the view to economy not being in the perfect working order which he had believed. He was glad to say, however, that all the difficulties connected therewith had since been overcome, and the machinery for turning out and drilling the plates was now working perfectly, and the work was being proceeded with as quickly as might be expected. They were now turning out nearly two spans per day, and, if they continued at this rate the line would be completed in 12 or 13 months. Difficulties were, however, always incidental to works where machinery was employed, and therefore they must not be too sanguine that the work would be finished in the time named. Comparing this railway with what he had seen of American overhead railways, this would be the best-looking overhead railway he had seen. As to the equipment of the line, they had not yet taken any steps, but, as previously indicated to the shareholders, electricity had been adopted as the propelling power. The progress in this as a motor was such that they had been advised by their engineer to postpone deciding upon the precise system until the last moment.

The report and balance-sheet were adopted, and a vote of thanks to the Chairman terminated the proceedings.

National Association for the Exemption of Machinery from Rating.

The annual general meeting was held at the Westminster Palace Hotel on Wednesday. Among those present were A. B. Winterbotham, Esq., M.P., William Mather, Esq., M.P., R. G. Mowbray, Esq., M.P., and many leading manufacturers.

The Report of the Executive Committee stated that they had to congratulate the members of the society on the great success which has so far attended its work, inasmuch that although it was found impossible to secure the presence of forty members of the House of Commons when the matter came up for discussion in the Session of 1889, the Bill for the Exemption of Machinery from Rating was read a second time on April 16th last, after a long debate, by a majority of 152 in a House of 330 members. It was stated that 169 petitions, containing the names of 21,149 persons, had been presented to the House of Commons in favour of the Bill. These petitions emanated from all classes, and included boards of guardians, corporations, chambers of commerce, trade unions, and large numbers of mechanics; while the petitions in opposition to the Bill contained only 348 names, almost entirely from Poor-law officials. Mr. Winterbotham and other members of Parliament explained the causes which had led to the failure of almost every private members' Bill in the past Session, and had prevented the passing of the Bill promoted by the society. It was resolved that the measure should again be introduced in the House of Commons in the next Session.

Votes of thanks were passed to the numerous members of Parliament who have supported the Bill, and to the Press for its almost unanimous advocacy of the objects of the society.

The report and accounts for the past year were adopted, and it was announced that the Court of Appeal had confirmed the decision of the Queen's Bench in the Chard case as to the rating of machinery, and there was an unanimous expression of opinion that a further appeal should be made to the House of Lords.

A vote of thanks was unanimously given to Mr. Humphreys Davies, the hon. secretary, for his valuable services.

CITY NOTES, &c.

BIRMINGHAM TRAMWAY COMPANY (LIMITED).—At the annual meeting of this Company on Thursday, the Chairman said that the year's operations had been very prosperous. The opening of the electric line in the Bristol-road had been demonstrated to be a scientific and mechanical success. What now remained was to see whether it could be worked with economy. Steam traction cost 3d. per mile; he believed the cost of electric traction would not be far from that sum.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 8th amounted to £4,863.

GRANGE SYNDICATE (LIMITED).—This syndicate has been registered with a capital of £2,000, in £5 shares, to develop and experiment upon Groth's electric tanning system, in conjunction with the patentee, upon terms of an agreement with Mr. L. A. Groth.

SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY (LIMITED).—The *London Gazette* of the 12th inst. states that at an extraordinary general meeting of the Sheffield Telephone Exchange and Electric Light Company (Limited), duly convened and held at the offices of the Company, Commercial-street, Sheffield, on July 11, the subjoined resolutions were passed, and at a subsequent extraordinary general meeting of the Company held at the same place on July 29th, they were duly confirmed:—"That it is desirable to reconstruct the Company, and, accordingly, that the Company be wound up voluntarily, and that Thomas George Shuttleworth, of Sheffield, chartered accountant, and William Johnson, of Sheffield, the secretary of the Company, be, and they are hereby, appointed liquidators for the purpose of such winding-up."

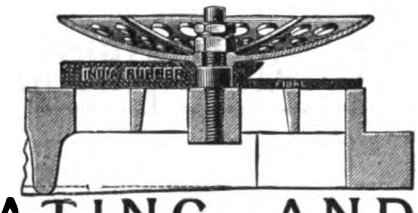
SOUTHEND TRAMWAY.—The tramway earned £6. 4s. 6d. on Saturday, the opening day; £25. 12s. 3d. on Monday; and £23. 4s. 7d. on Tuesday.

STOCK EXCHANGE.—Application has been made to the committee to appoint a settling day in and to grant a quotation to Elmore's Wire Manufacturing Company (Limited) ordinary shares; and to allow the Electric Construction Corporation (Limited) shares to be quoted in the official list.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 8, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,761.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 26th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 640.—Vol. XXV. FRIDAY, AUGUST 22, 1890. Price Fourpence.

NOTES.

On September 3rd, the sixtieth meeting of the British Association will be opened at Leeds by the President for the year, Sir Frederick Abel. Leeds offers several advantages on account of the great variety of industries which are carried on in its neighbourhood, affording opportunities for visits to a number of very interesting factories. A matter of greater importance to most members is the exceptional facilities which the district offers for excursions and picnics, both on account of the beautiful scenery and places of interest, including at least one abbey for each section, and a railway service which is unequalled in any other part of the country, and which will surprise those who are accustomed to the railways of suburban London.

Up to the present time the following Electrical Papers have been offered, and these are chiefly in Section A. They include "Regional Magnetic Disturbances on the Weald," by Profs. Rücker and Thorpe. "Suggestions towards a Final Determination of the Ohm," by Prof. J. V. Jones. "On the Electrostatic Forces between Conductors carrying Currents," by Prof. Oliver Lodge. "The Molecular Theory of Induced Magnetism" (with exhibition of a model), by Prof. J. A. Ewing. "The Effect of Oxidation on the Magnetic Properties of Manganese Steel," by Mr. L. T. O'Shea; and four short papers by Mr. Swinburne, on "The Compensation of Alternating Current Instruments," "The Resistance of the Human Body under Direct and Alternating Pressures," "Notes on High Vacua;" and, in conjunction with Mr. W. F. Bourne, "Testing Iron." In Section G, a paper on the "Lineff Tramway" will be read by Mr. Kapp; on the "Column Printing Telegraph," by Mr. Higgins (described in *The Electrician*, December 23rd, 1887, vol. xx., page 155); "Alternate *v.* Continuous-Currents, in Relation to the Human Body," by Mr. H. N. Lawrence and Dr. Harries; "Secondary Batteries," by Mr. Barbour Starkey; "The Victoria Torpedo," by Mr. G. Read; a Paper probably on the Distribution of Electricity, by Major-Gen. Webber; and one or more Papers by Mr. Preece. Although this list is brief compared with that of last year, communications may of course be expected from Sir W. Thomson and others, together with reports of various Committees, including one on Electrical Units.

Few districts have been so coveted by the purveyors of electric light as that of the City of London. Mr. Crompton quietly selected the best bit of Kensington before any one else was ready; and the St. James and Pall Mall Company appropriated, without much opposition, the important bit of Club-land which had been pointed out by Prof. Forbes. The London Electric Supply Corporation cast their net of wires far and wide; but the City has listened to no one but those indefatigable members of the Commissioners of Sewers who have made reports, received reports, and referred reports from one sub-committee to another since the spring of 1883. Mr. Preece has probably examined and reported upon as many tenders, offers, and schemes for lighting the City during the last seven years as would suffice for the illumination of every town in England, if only they were practicable. At Major Marindin's inquiry, the representatives of the City appeared to be struggling against the introduction of electric light into their sacred precincts, as though it were some pestilence. No concession or compromise would please them, nor could anyone else comprehend the peculiar privileges and ancient customs which they feared would be imperilled.

It would have been hard, indeed, if the Brush Corporation had not succeeded in securing a slice of the City after the repeated efforts which they have made; but it was scarcely to be expected that a similar share would have been given to a firm who have not yet done any supply in London. Excellent as the results of Messrs. Laing, Wharton, and Downs' work has been at Taunton, Exeter, Weybridge, and other places, we have yet to see how they will carry out street work under the special conditions imposed by the City. There is little doubt, however, but that it will be well done. The third and westerly district will not be allotted this year; but we understand that a keen competition is going on between various firms, among whom the two we have mentioned are included. The first step that has to be taken is to find the capital for carrying out the work. There will not, probably, be any difficulty about this, as the success of electric supply has been so firmly established during the last two years that the satisfactory lighting of the City is assured.

No doubt those who have studied the matter can judge of the relative values of the three districts into which the City has been divided. The cream of the lighting has not been taken by such private plants as those which supply the theatres and hotels and other important establishments of the West End. These can well compete in the matter of price with supply companies, since they have no street mains to lay

Digitized by Google

and maintain, and need no staff worth mentioning. The bulk of the lighting will cease at the time when the load at the West End is heaviest; but the demands when a sudden fog comes on will tax the stations severely. There should be a good field for motors for hoisting and for lifts, especially in the Eastern District; while motors for printing should form an important item in the Western Division. When the mains are laid down in Salisbury-court we shall be prepared to accept a fifteen horse-power motor, with all the latest improvements, and will make no charge for giving it a few years' steady testing on our presses.

MANY of the improvements in the steam engine of to-day are due to the demands of the electrical industry, while the high-speed engine, though introduced some years ago on grounds of economy of steam and reduced first cost, has established itself, in spite of the prejudices of the old school of engineers, mainly on account of the needs of electric lighting. Prof. ROBERT THURSTON, in the article of which we give an abstract in another column, says that the demands for uniformity of speed exacted by the requirements of cotton-spinning machinery have been met by the use of governors which control the speed to within 1 per cent. of the mean, and within a total range of 2 per cent.; but that in electric lighting the range considered allowable is often half this amount, and he further adds that some makers guarantee that the fluctuation shall be imperceptible from full load to no load. In former years those who required uniform speed had great difficulties in compelling engine-builders to supply good governors. The old slow-speed governor of WATT, acting on a throttle valve, was good enough to prevent a runaway, and in many cases the driving shafts were burdened with huge fly-wheels in the mistaken idea that these will cure the evil which the introduction of the high-speed governor did much to alleviate.

COTTON spinners in this country, remembering the struggle which they had for regular speed, are generally under the impression that their engines are singularly perfect in this respect. We remember a case where a water-wheel, a beam engine, and a horizontal engine all strove together to do their best to drive a mill. A dynamo was put down for some experimental lighting. Complaints arose about irregular light, and before long, about lamp breakages; the latter indeed caused the lighting to be abandoned, in view of the probable cost of renewals. Nothing would induce the proprietors to believe that their speed varied; and the suggestion of an electrical regulator was tantamount to an insult to the venerable driving plant. Makers of accurate governors have successfully used the Moscrop speed indicator to give legible evidence of irregular speed and the efficacy of their appliances; and their results are often very remarkable. The range of one or two per cent., however, which Prof. THURSTON speaks of, has, we believe, been unknown among our textile manufactures until the last few years, and very rarely is it to be found at present. For dynamos coupled direct to separate engines, an exact control is not of great importance, as the inaccuracy of the engine can generally be satisfactorily accommodated in the compounding of the dynamo. The subject is being discussed by Mr. SWINBURNE in a series of articles in *Industries;* we give an abstract of the first one in this issue, as the subject is of very great importance.

OF making of new dynamos there appears to be no end, especially on the other side of the Atlantic, although on this side we seem to have settled down to two or three distinct types. This is, at least, the case with direct-current machines, and will probably soon be true also of alternators, in which at present some little uncertainty still exists, doubtless to be rapidly removed. The new welding machine of Prof. THOMSON, which we illustrate this week, is an attempt to generate the current at the welder, instead of conveying it as a high-tension current to the welder, and there transforming it into a low-tension current by means of a stationary transformer. It will be remembered that Prof. THOMSON started his welding work by using a direct-current dynamo on which the welder was placed, thus avoiding the necessity for conveying the large currents by large and costly conductors. There is a partial return to this plan in the present case, the chief difference being that the machine is made to give an alternating current, and does this by means of a fixed armature so as to avoid the collection of the current by rubbing contacts, a small coil on the fixed armature being used in conjunction with a commutator for the purpose of exciting the field by a "re-dressed" alternating current. There would seem to be no particular advantage in this plan. The use of a dynamo at each spot where welds are made is attended by practical disadvantages. Space must be found for the dynamo; and, although this may not be a serious matter, the further disadvantage of having to provide means for driving the machine must be inconvenient in many cases. The plan of having the generating plant at a distance and placed where it can readily be looked after, seems alone sufficient reason for adhering to the alternate-current arrangement with a transformer. As to the dynamo, the resemblance to the old AYRTON and PERRY motor and to the "Topf maschine" of SIEMENS shown in the Paris Exhibition of 1881, will at once strike our readers, who will doubtless agree with us that Prof. THOMSON, in working up this old idea for his new and interesting purposes, has not made a very good use of his material.

THE treatment of magnetic induction as something produced in the iron, alluded to by Dr. FLEMING in another column, and the use of the term gilb to signify the unit of induction, would remove a difficulty which many students have felt in connection with the notion of lines of force. That so many ampere turns under certain conditions produce so many lines of force is simple enough; but what would happen if the number of lines were reduced to less than one? What kind of thing is half a line of force? It is true that the idea of tubes of induction was invented to obviate this difficulty; but we prefer the gilb.

A FRESH determination of the ohm has recently been made by M. WUILLEUMIER, who has arrived at results in very close

Digitized by Google

agreement with the best values yet obtained. The measurement of resistance, the dimensions of which in electro-magnetic measure are those of a velocity, generally resolves itself into the determination of a speed and a length, other measurements being of minor importance; and the best methods are those for which the formula required is of a very simple character, involving but few quantities, and in which the length and time elements are directly apparent. These advantages are all secured in the modification of LIPPMANN'S electro-dynamic method, adopted by M. WUILLEUMIER. A current of about 12 amperes was passed through a long solenoid and a standard coil having a resistance of about $\frac{1}{3}$ ohm. A small coil was turned at a uniform speed within the solenoid; and, at the point of its revolution at which the induced electromotive force is greatest, contact is made with the two extremities of the standard coil, a capillary electrometer being used to test the balance between the induced electromotive force and the difference of potentials set up by the current in the standard coil. By assuming the solenoid endless, the formula becomes very simple indeed, and the correction caused by its finite length is obtained entirely by experiment, and in an easy way. After several attempts had been made to secure a better one, the method finally adopted for measuring and governing the speed was very similar to that used by Lord RAYLEIGH in his experiments; and it is curious that the friction of a cord against the hand forms the best mode of regulating the constancy of the speed in such experiments. The apparatus employed was remarkable for its large dimensions, and we believe it is the first time that a current so large as 12 amperes has been used for the absolute measurement of resistance. The employment of the capillary electrometer in this connection is also a novelty. M. WUILLEUMIER finds 106·27cm. as the length of the mercury column, of one square centimetre section, whose resistance is one ohm.

ON the general question of the resuscitation of dormant patents, in view especially of the recent attempt, not yet abandoned we believe, to revive and claim royalties on the very ancient patent of Mr. LANE-FOX, we cannot help thinking that the rule in force in more than one foreign country, that a patent must be worked by the inventor within a year or two from the sealing of the patent, is not without its advantages; and we commend this point to the attention of our legislators. It cannot be to the general interest of the community that trade and industrial energy should be threatened with surprises of this sort. No one grudges an inventor an ample remuneration for his work; but if he deliberately allows others to do it without protest for many years, it is doubtful whether he is equitably entitled to any recognition other than the honour of priority of invention; and he must not be surprised if resistance is offered, such as that of the Defence Association whose circulars will be found in another column.

BY the courtesy of the officials of the Electric Lighting Department of the Board of Trade, we are able to give in this issue a complete list of the Provisional Orders which have received royal assent during the recent Session of Parliament. The information may be considered as official and thoroughly accurate, and is now published for the first time.

THE regulations issued by the Boston Manufacturers' Mutual Fire Insurance Company do not contain any solution to the difficulties which are felt so keenly in this country. The word "approved" often occurs in the specifications of architects and of engineers, but "approved substantial supports," "an approved, moisture-proof, non-inflammable, insulating tubing," are expressions that should not be used in the rules of an insurance office. Most people will agree with Major FLOOD-PAGE that there should be but one set of rules, and we are not disposed to quarrel with his selection of those of the Phœnix office; but he does not touch on the sore point. It is not the rules, but their interpretation that causes the trouble. If this or that material or method may sometimes be used, and may sometimes be condemned, why not say at once: Rule 1,—Wires, insulated in an approved fashion, are to be erected in an approved manner; Rule 2,—Switches and all other accessories are to be of an approved pattern?

Electric Lighting at Berlin.—The electric light is to be adopted at all the railway stations in Berlin and its suburbs.

Electric Railway at Prague.—The Town Council has granted a concession for an electric railway from the Belvedere to the Baumgarten.

Woolwich.—The Local Board have given their consent to the Woolwich District Electric Light Company lighting the town with the electric light.

A New Professorship.—At the commencement of the next Session of the Conservatoire des Arts et Métiers a chair of Industrial Electricity will be created.

New Board of Trade Rules.—A set of rules relating to the method and procedure for applications for licences and Provisional Orders was issued on Tuesday last.

New Portuguese Cable.—The Government has been authorised to lay down and work at the expense of the State a cable to connect Lisbon with St. Michael, Terceira, and Fayal.

Telephone Communication between Ulm and Friedrickschafen.—A double conductor, 104 kilometres long, of bronze wire, three mm. in diameter, is now at work between these towns.

La Societe Parisienne de Force et d'Eclairage.—This Company has been definitely constituted. M. Griolet, Administrateur of the Chemins de Fer du Nord, has been nominated as President of the Executive Council.

Traction by Accumulators at Hagen.—We are informed that the Company into which Messrs. Müller and Einbeck's business has been turned has equipped a car with Tudor accumulators for running on the Hagen tram lines.

Train Lighting in Russia.—The Russian Government, anxious to see the wholesale introduction of electric lighting for trains, has decided that all the carriages of the State railways are to be lit by electric light after this month.

The Electric Meter Competition at Paris.—We would remind our readers that instruments intended for this competition, of which we published the rules some little time back, should be sent in before the end of the present month.

Sheffield.—It was decided at a meeting of the Town Council last week to decline to approve of the applications made by the Electric Installation and Maintenance Company and the National Electric Supply Company for Provisional Orders, inasmuch as the Council intend themselves to apply for an order.

Digitized by Google

Telegrams to Heligoland.—The charge per word for telegrams to Heligoland has been reduced from 4½d. per word to 2d. Two new cables, it is stated, will be laid down between Heligoland and the mainland. One will be laid to Wilhelmshaven, and the other will pass over the Island of Amrom.

Chester.—At a quarterly meeting of the Town Council it was recommended that the Bill confirming the Provisional Order authorising the supply of electricity within the city having received the Royal assent, it be referred to the committee to report as to the course most advisable to take for putting the powers of the order into execution.

Telpherage.—A concession for a telpher line for postal service between Buenos Ayres and Monte Video has just been granted to a Company. In the distance of 300 kilometres which separates the two cities the line will cross the estuary of the Plata, the width of which at this point is 30 kilometres. The passage of the postal boxes will be made in two hours.

University of Glasgow.—The next session commences on November 4th. Courses in Civil Engineering and Mechanics are conducted by Prof. Archibald Barr, D.Sc., M.I.C.E., and Naval Architecture and Marine Engineering by Prof. Philip Jenkins, M.I.N.A. Prospectuses and other information may be obtained from the Assistant Clerk at the Matriculation Office.

Electric Traction at Gera.—According to the *Elektrotechnisches Echo*, the Town Council of Gera have decided to grant the application of Messrs. Hostmann and Co., of Hanover, for permission to work three tram lines by electricity. The system adopted will be that of Sprague, whose patents for Germany have been acquired by the Allgemeine Elektricitäts Gesellschaft.

Telephone Communication in Italy.—From the *Elektrotechnische Zeitschrift* we learn that telephonic communication is to be established between Rome and the following towns: Naples, Florence, Genoa, Turin, Milan, Venice, and Spezzia; also between Turin and Milan, Milan and Venice, Genoa and Turin, Genoa and Florence, Naples and Palermo, and Messina and Palermo.

Worcester.—At the meeting of the Watch and Lighting Committee last week, Alderman Hill in the chair, the Town Clerk reported that electric lighting powers had been conferred on the Corporation under a Provisional Order. He suggested that some electric lighting companies should be communicated with in order to ascertain upon what terms they would carry out the work for the Corporation. The matter was referred back to the Lighting Sub-Committee.

Monopoly of Gutta Percha from Sierra Leone.—The President of Liberia has issued a proclamation, securing to the Liberian Concession Company (providing they comply with certain conditions previously agreed upon) the sole right of exporting all caoutchouc or rubber and gutta-percha gathered or collected within the Republic; and also announces that the violation of their said right by any individual shall be deemed a misdemeanour, punishable by a fine of not less than £1,040, nor more than £2,080.

Electricity at the North-West German Industrial Exhibition at Bremen.—The Electrical Section of this Exhibition is said to be of a very complete nature. Most of the well-known German firms have sent exhibits. The electric lighting is in the hands of Messrs. Siemens and Halske, Schuckert and Co., and the Bamberg Electric Company. The working of a street railway from the city to the Exhibition shows, it is said, for the first time in Germany the application of the Thomson-Houston system to traction work.

Proposed Extension of the Bradford Station.—At a special meeting of the Gas and Electricity Committee of the Bradford Corporation, held on the 8th inst., tenders were considered for the supply of engines, &c., required for the extension of the electricity works. The matter was referred to the Electricity Sub-Committee. The latter considered a tender of Messrs. Siemens Brothers for the supply of engines, &c.; but the prices in it were regarded as too high, and the town clerk was instructed to write with a view of having them reduced.

Telegraphic Extension to Tonkin.—A junction has recently been made between the telegraphic system of China and that of Tonkin, at a spot about 220 yards from the well-known port, Nam-Quan. This extension will enable the consulate of Longtchéou to be placed in direct telegraphic communication with France. According to the *L'Ingénieur-Conseil* there will be no difficulty in communicating with the Chinese offices, since by means of a special and well-understood code it will be possible to translate the telegraphic characters and transmit the messages to their destination.

The National Electric Light Association.—Last week we gave a list of the Papers to be read at the Convention at Cape May, New Jersey. The following particulars given by *Practical Electricity* are at least as interesting as the titles of the communications, and might be studied by one of the numerous committees of the British Association:—"The way the time will be spent there: Breakfast from 6 to 10:30. Morning session of Convention from 10 to 12. Bathing from 12 to 1. Dinner from 2 to 4. Afternoon session of Convention from 4 to 7. Supper from 7 to 9. Orchestral concert or hop from 9 to 11."

Telegraphists.—In answer to Mr. P. O'Brien on Friday night last, Sir H. Maxwell said, the scale introduced on July 11th last fixed the wages of second-class telegraphists at 12s. a week for the first year, at 14s. a week for the second year, and at 18s. a week for the third year, thereafter rising by 2s. annually to 40s. a week. This scale is on the whole better, far better, than the one it superseded. In connection with the old scale, however, there was an arrangement under which a learner, if fully qualified, could receive 16s. on appointment, and it is being considered whether a similar advantage should not be given to those learners whose employment began before the new scale was introduced.

Lighting of the Natural History Museum.—Sir G. Campbell, on the vote for the British Museum, asked in the House of Commons whether arrangements could not be made for the lighting of the Natural History Museum so that it could be used in the evening. Mr. Jackson said that, as the introduction of the electric light was a matter of experiment, it had been thought advisable to begin with the British Museum, because it was nearer to the masses of the people, and was more easily reached by them than was the Natural History Museum. The same pressure had not as yet been put upon the trustees to light the Natural History Museum, but experiments would be made with a view to the illumination of the building should it ultimately be determined upon.

Gas and Electricity.—At the half-yearly meeting of the Liverpool United Gas Light Company, on the 19th inst., the Chairman stated that he had never been one of those who poohpoohed the question of electricity. He always recognised it as a most important factor, and could only say now, as he had done before, that there was nothing so far to cause the slightest uneasiness to the proprietors of gas stock. It was quite true that the consumption of electricity in Liverpool was increasing, and therefore to a certain extent the consumption of gas by those who had used it before was decreasing; but the decrease was by no means to be compared with the increase that was going on. For, in spite of what electricity had done, the consumption of gas in Liverpool during the past year had increased by 2 per cent. Of course, they must look to an extension of electricity, but they might just as safely conclude that other uses for gas would be found, that a steady consumption of gas would continue, and that the property of the company would be just as safe now as it had been in the past.

The Telephone Monopoly of the German Post Office.—Until lately the German Post Office claimed the sole right of erecting or licensing private telephone installations, thus prohibiting the development of a convenient means of communication, and excluding the legitimate industry from a branch which ought to be its domain. Messrs. Mix and Genest, of Berlin, determined to test the legality of this proceeding in a court of law, and brought an action against the German Government claiming that the German Post Office had no right to restrain or prohibit the plaintiffs from erecting and maintaining private

Digitized by Google

telephone installations, (a) between buildings belonging to the same landlord, but situated at a distance from each other, and separated by property of other landowners, or by public roads or otherwise; (b) between property belonging to different landlords, *i.e.*, from one part of a city to another. This claim was decided on July 10th last, thus putting an end to a state of things which has lasted too long to the disadvantage of those interested in this daily progressing industry.

Fire at the Edison-Swan Factory.—A fire broke out in the depositing rooms of the Edison and Swan Company's Factory at Ponder's End on Tuesday morning. This portion of the factory is divided from the remainder by a thick party wall of great height. The cause of the fire was, it is stated, an extra pressure, by which an electric spark ignited some benzoline used in the work. The fingers of the girl using the benzoline were hurt, but about 50 other girls to whose benches the fire quickly spread were got out of the place uninjured. The local fire brigade attended, but their efforts were confined to preventing the flames from going further. They thus saved the remainder of the premises, but the depositing building was destroyed. The factory has been carefully constructed in separate fireproof portions, on the same principle as the water-tight compartments of a ship, with the view of confining any outbreak of fire to the room in which it might originate. In the present case we are glad to learn, on making inquiries, that the damage has been entirely confined to the room in which it broke out. Owing to the large stocks in hand, the Company will experience no difficulty in executing orders, but they ask the forbearance for a few days of customers from whom they have orders for special lamps.

Electric Light at the Agricultural Exhibition at Vienna.—From the *Neue Freie Presse* we learn the following particulars of Siemens and Halske's installation at this Exhibition:—16 Siemens and Halske dynamos are driven by 11 steam engines supplied with steam from six boilers. The machines supply 400 arc lights and 2,000 incandescents. The arc light machines work at 300 volts and can each supply 72 arcs of 2,000 normal candle-power, and taking 10 amperes. Altogether, these machines supply 400 arcs in the Rotunda and the Park. The incandescent lighting machines, five in number, can each feed 500 16 candle-power lamps at 110 volts. For the illumination of the fountains two separate dynamos are employed, supplying together 660 amperes at 80 volts. There are altogether 72 arc light circuits, six incandescent circuits, and two for the fountains. Their total length is about 60 kilometres, of which about 17 kilometres consist of lead-covered cables, placed underground. This installation is said to be the largest in existence in Austria. About 675 horse-power are converted into light. Up to the present the installation has been run without the slightest hitch of any kind.

Train Lighting in Australia.—The Railway Commissioners of Sydney have recently made a very successful experiment in connection with the lighting of railway cars with electricity. The system now introduced is exceedingly simple. Two accumulators, each containing 14 Crompton cells, and weighing about half a ton, are placed under the carriage, and at convenient distances between the bogies. These are charged from the dynamos at Redfern required for the electric lighting of the station, and they are calculated to feed the six 16 candle-power Thomson-Houston lamps for about 14 hours. The *Sydney Mail* says that it was decided to use the Crompton cells, because they take up much less space than any other, are of less weight, are more perfectly insulated, and are more easily recharged. The system is completely under control, and the power of the lights can be regulated at will; and, what is of importance, the cost, it is estimated, will not exceed that of gas. The Commissioners first of all intend to apply the change to the sleeping cars attached to the express, and then probably one of the suburban trains will be lighted throughout by electricity. In the summer time the change will be appreciated, for the heat of the cars at night will be materially lessened.

The Generation of Electricity by the Tide.—A French engineer, M. Decœur, proposes to supply electric power to Paris by utilising the flow of the ebb and flood on the coast. For this purpose he intends to construct, near Havre, two large basins joined to each other, into one of which the sea at flood-tide flows over a dam, while during ebb it flows out of the other into the sea again. At the inlet and outlet M. Decœur proposes to erect a number of powerful turbines for transmitting the energy of the water. The mechanical energy thus produced M. Decœur estimates, with a tide of 18ft., which is the average at Havre, at six horse-power per hectare of basin area. He intends parting off by means of a dam 16½ miles long an area of 7,000 hectares between Havre and Tancarville from the sea and the Seine respectively, and thus creating 42,000 horse-power, which power he transforms into electrical energy and transmits to Paris. M. Decœur's scheme is looked upon with favour, and although the estimated net profit of 8,500,000fr. is too high, the *Morning Post* says that there are indications that it will ultimately be carried out. In his Presidential Address to Section A at the British Association Meeting of 1881, Sir William Thomson pointed out the impracticability of such schemes; and on the subject of building dams said, "If so much could be done, it would in many cases take only a little more to keep the water out altogether, and make fertile land of the whole basin."

Improving the Dynamo.—Under this title appears the following editorial note in the *Electrical World* of New York; some of the suggestions are noteworthy, but in this country commutators are not unfrequently the pride both of the manufacturer and of the attendant:—"It is a very remarkable fact, that in less than a score of years the dynamo should have reached so high a state of development that so far as efficiency is concerned there is little left to be done. The best dynamos to-day actually return as electrical energy more than 90 per cent. of the power used in driving them. Much beyond this we cannot hope to go, for we have no material of infinite conductivity, no insulator against magnetism, and no perfect lubricator. Even now slight increase in efficiency is often gained at too high a cost in material and labour. But the dynamo is by no means perfect yet; and it behoves inventors not to sit down and wait for the much-rumoured and never-seen methods of obtaining electricity direct from heat, but to sharpen their wits and go to work. And first of all, let them turn their efforts against that root of all electrical evil, the commutator. It has no virtues to speak of, and is a most fruitful source of trouble. We already have alternating dynamos quite free from its malign influence, and it is high time we had a continuous current machine of a similar sort. The problem is difficult, it is true, but there is no reason to think it impossible, and we commend it to the attention of the inventors who now fritter away their talents devising cruel and unusual forms of field-magnets. The commutator must go."

Fire Insurance Rules.—Major Flood Page, writing to the *Times* of yesterday, says that, having been consulted as to the rules that should be adopted by the Corporation of a small town, he communicated with the chief fire insurance offices. He gives the following analysis of the replies. The 33 offices from whom he has heard may be divided thus:—(*a*) Ten offices use the Phœnix rules. (*b*) Six offices use the Institution rules. (*c*) Ten offices have each their own special rules. (*d*) Seven offices have no special rules, but deal with each case as it arises. (*e*) Seven of the above offices send out a list of questions which must be answered by those who wish to have electric light in their houses. On the ground that the foundation on which other rules have been built seems to be that of the Phœnix rules, he urges the other offices to adopt these, and gives the following quotation from the preface:—"Notwithstanding the number of years these rules have been in use, not a single instance of fire has occurred, neither has the slightest injury happened to any person from any electrical installation that has been placed up in compliance with them." The Major admits that he is aware that rules are not in themselves sufficient. Much will always depend on the care with which the inspector satisfies himself that the rules have been faithfully and properly carried out. Nevertheless, if all houses are wired on one principle, the work of the contractors will be simplified, it will assist the workman, and will facilitate the inspections which must always take place when the wiring is complete. And as he believes that the Phœnix rules have served as a model for every office which has special rules; as

Digitized by Google

the Phœnix rules have stood the test of time and are known throughout the world; as they have been adopted in integrity by many of the offices; as they are understood and approved, except in one small detail, by the electrical trade, and are practically safe, he ventures to express the hope that offices generally will adopt them, unless and until they can find better and safer rules by which to work.

Cataphoric Medication.—This process of accelerating the passage of drugs through the skin by endosmosis in the direction from the positive to the negative pole, which is regularly practised, under medical sanction, at the Institute of Medical Electricity, has been experimented upon by Mr. Edison. He tried the application of the method to a patient suffering from an acute and typical form of gouty concretions, in December, 1889. This person volunteered to try the effect of the method. He was 73 years of age, and had lived an active healthy life until ten years previously. Concretions commencing continued to increase slowly until they assumed large proportions. The joints of the fingers were almost obliterated by concretion. The girth of the little finger of the left hand was, by careful measurement, 8·6 cms., that of the corresponding finger on the right hand even greater. The current generated from Mr. Edison's laboratory 120 volt dynamo, passed through about 5,000 ohms resistance, and entered a jar containing an aqueous solution of lithium chloride, density 1·08, in which the patient immersed his left hand up to the wrist. His right hand was similarly immersed in a solution of common salt. The current, after passing through his body, left the latter jar by a negative electrode. It was found that he could stand 20 milliamperes without inconvenience, and this strength of current was steadily applied for six days during four hours daily. At the end of that time the girth of the left-hand little finger was distinctly reduced to 8·2 cms.; the patient also experienced freedom from pain after the first day's treatment. He continued the treatment for two days more during the week following, and then the journey to and from the laboratory exhausted his strength. The finger girth, after fourteen days from the date of commencing treatment, was 8·0 cms., a total reduction of 0·6 cm. This was estimated to represent a reduction of 3 cm. of concretion on this particular finger, whose form facilitated accurate measurement. His general condition, beyond the weakness resulting from unaccustomed journeying, was temporarily ameliorated.

Efficiency of the Transformer.—Writing to the *Electrical Engineer* of New York, the source of the Papers of which we gave abstracts in our recent issues of July 18th and 25th, Mr. Swinburne says:—"In common, no doubt, with most engineers on this side of the water, I have read Messrs. Humphrey and Powell's Paper on the above subject, reported by you, and have been surprised at the results obtained. The loss by hysteresis comes out astonishingly small. There is one point, however, in the report of the Paper which is not clear, and that is the method of measuring the instantaneous values of the primary currents. The instantaneous electromotive force on two lamps in the primary circuit was taken and divided by the resistance of the lamps, the lamps having been previously tested throughout their range, so that a resistance corresponded to each electromotive force on them. There is nothing in the Paper to say whether the resistances taken in determining the instantaneous currents were those corresponding to the instantaneous electromotive forces, or to the effective electromotive forces. On looking up Prof. Ryan's classical Paper, I find the same uncertainty. I hardly like to suggest that Prof. Ryan and Mr. Merritt, or Messrs. Humphrey and Powell have made a slip here; but there does seem to be room for an error that would bring out the efficiency too high, especially at light loads when the lamps in the primary would be dull. The resulting determination of the power lost would be chiefly affected by the part of the current curve under the peak of the electromotive force curve, which, assuming the slip to have been made, would be too low. The top of the magnetising current would come too high, but this would not correct the error, as there is no electromotive force then. I do not see how this possible error could give rise to greater inaccuracy in one Paper than the other; even Prof. Ryan's tests of hysteresis losses are small. The hysteresis also varies with the load, which is curious. Prof. Ryan suggests that at full load the force on the coil shakes the iron. The force should not exist in a transformer, and depends on what Prof. Ryan calls the leakage and not on the total induction through both coils. Moreover, if the application of external energy, as in shaking iron, prevents loss from hysteresis appearing in the circuit, it is probable that the energy is lost as before, but is now supplied mechanically. But in the transformer the mechanical energy is itself supplied electrically, and so the loss by hysteresis would not be lessened by the shaking due to forces acting on the coils. I mention these points merely for elucidation; American colleges do practical work that puts ours to shame, so it would be unbecoming to attempt to criticise it from this side of the Atlantic."

Telegraphs and Electric Railways.—The Commercial Cable Company land their cable at Coney Island and continue it with an underground cable through Ocean Avenue and Brooklyn into the middle of New York, practically making the terminus of the cable in Wall-street, instead of landing at some secluded spot, and repeating the messages by a land line. The underground cable has four cores, separated from each other by about one thirty-second of an inch. The cable is connected to one of these, the diagonally opposite one is soldered to the sheath of the sea cable, and is used as an earth; the other cores are kept as reserves. Mr. Cuttriss writes to the *Electrical Engineer* of New York to say that everything has gone well until a few months ago, when they were troubled by occasional kicks on the receiving instrument; sometimes they would be so strong as to obliterate a signal. As these kicks are nothing unusual during the summer months, owing to thunderstorms and other atmospheric disturbances, they were for some weeks attributed to such causes. During this period it was also noticed, when testing the cable, that the mirror seemed to be very unsteady, and had erratic movements, which denoted by their abruptness that the cause of disturbance was near this end of the cable, and was such as might be produced by a small fault. To satisfy himself on this point, he had the cores cut at the cable house on Coney Island, and while he was testing the undergrounds, the electrician at Nova Scotia (the distant end) was also testing the sea cable. The results showed that both the undergrounds and the cable were in perfect condition, but it was observed that there was some disturbing cause in their neighbourhood; as, after perfectly discharging the cores, they would in a few seconds become quite heavily charged, always with the same potentials. So far, we had arrived at only negative results, as the kicks, &c., were still present on joining up the working instrument. About this time it came to his knowledge that there had recently been an electric railroad established, running from Prospect Park, Brooklyn, to Coney Island by way of the old Coney Island horse car road. It must be remembered that ocean cables are operated by a recording instrument that is so sensitive that a current of $\frac{1}{1000}$ of a milliampere will produce a distinct working signal; hence it is quite conceivable that, although the electric road does not in any part of its route approach our underground cables nearer than about half a mile, disturbances might be produced by the power used in starting and running the cars. The telephone was connected to the cable and a local earth; the sounds were so loud that they could be heard with the telephone a short distance from the car. The testing galvanometer, a Thomson astatic, of course could not pick up such rapid vibrations, but it shows deflections and kicks to such a degree that we have sometimes been obliged to give up testing and try at a more favourable time, such as 1 or 2 a.m. when the cars have stopped for the night. With telephones and ordinary telegraph instruments the use of a metallic circuit is a good protection, but in the present case it is proved that a metallic circuit through the disturbed district does not grant immunity from serious disturbances. One point is still to be determined in regard to this phenomenon, namely, to ascertain for a certainty whether the effects produced are to be attributed to conduction through the earth and water to our armouring, or if it is an inductive effect. The fact remains, that if electric roads should be greatly augmented in our vicinity, the disturbances will be seriously increased. The tests show our undergrounds to have a dielectric resistance of about 350 megohms per mile, so the idea of any leakage cannot be entertained.

MAGNETISM IN IRON AND OTHER METALS.*—XXVIII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 402.*)

§ 105. **Results of Optical Measurements.**—The general results as to the action of strong fields which the optical method has yielded in the hands of Du Bois, are in complete agreement with those obtained by means of the isthmus method and narrated above. The magnetic force was not pushed to such high values, but the values were high enough to show that a close approach to a limiting maximum of I had been reached. With nickel, the force H was raised to nearly 13,000, with cobalt to 8,500, with steel to 4,500, and with soft iron to 2,500. The limiting values towards which I tended appeared to be 530 in nickel, 1,200 in cobalt, and 1,630 in steel (a hard English cast steel). In the case of iron, the experiments were rather less satisfactory, but pointed to a limit between 1,700 and 1,750. These values are given for observations made when the specimens were at a temperature of 100°C.; at ordinary temperatures the values would be rather greater, as was shown by comparative tests at 100° C. and at 0° C. It is clear that these numbers are in good general agreement with those that have been stated already, §§ 98–102. The following data are taken from Du Bois' Paper. Table XX. relates to a specimen of cast cobalt, tested at 100° C., containing 5·8 per cent. of nickel, and 0·8 per cent. of iron. An additional observation, made in the strongest field, showed that I at 0° C. was 1,232. Table XXI. relates to a specimen of hard-drawn best nickel wire, stated to contain 99 per cent. of nickel. Here, again, a low temperature observation in the strongest field made the value of I at 0° C. to be 579.

TABLE XX.—*Cobalt in Strong Fields at 100° C.*

H	B	I	μ
860	14,180	1,060	16·49
2,500	16,750	1,134	6·70
4,800	19,550	1,174	4·07
6,870	21,710	1,181	3·16
8,350	23,330	1,192	2·79

TABLE XXI.—*Nickel in Strong Fields at 100° C.*

H	B	I	μ
550	6,420	453	11·67
3,410	9,920	518	3·12
6,290	12,850	522	2·57
9,600	16,250	527	1·69
12,620	19,220	525	1·52

On making optical observations with a specimen of Hadfield's manganese steel—the non-magnetic steel spoken of in § 70—it was found that the amount of magneto-optic rotation of the polarised ray varied considerably when the ray was reflected from different parts of the same polished surface, from which Du Bois infers that this material is essentially heterogeneous, having relatively strongly magnetic layers interposed between non-magnetic or feebly magnetic portions of the mass. He supposes the structure to be laminar, but so fine-grained that to ordinary tests it appears homogeneous.

§ 106. **Magnetisation of Magnetite.**—Du Bois has applied his optical method to obtain absolute measurements of the magnetisation in strong fields of a crystal of magnetite (the magnetic oxide of iron, Fe_3O_4) which is the only substance that shares with iron, nickel, and cobalt the distinction of being strongly magnetisable. The results show† that there is a limiting maximum of I in magnetite with the value of about 350, and that saturation is practically complete with a force H of 1,000 or 1,500 units.

§ 107. **Experiments with Ellipsoids.**—Reference has been made to the preliminary experiments with ellipsoids by means of which Du Bois determined the values of Kerr's constant in specimens of the same metals as were afterwards tested in stronger fields by the optical process. The experiments with ellipsoids were important, not only as a means towards that end; they are interesting in themselves because they deal with a portion of the range in regard to which we have no other experimental data, namely, the portion which extends from H = 200 or so to H = 1,200 or 1,300. With respect to higher forces, we have the results of the isthmus and of the magneto-optic methods; with respect to lower forces, we have, of course, a mass of data; but between the limits named there is a gap which these experiments with ellipsoids are the first to bridge.

The magnetic force was applied by means of a coil, and the specimen was an ovoid or prolate ellipsoid of revolution 18cms. long, and 0·6cm. in diameter, which was kept at a uniform temperature of 0°C or 100°C. by applying ice or steam. Its magnetisation was measured by the ordinary magnetometric method, a compensating coil being used to balance the greater part of the action of the magnetising coil upon the magnetometer. The ratio of diameters being 1 : 30, a correction of 0·052 I had to be subtracted from the magnetic force due to the coil to find the true magnetic force (*see* § 26).

Du Bois gives the results in the form of curves connecting H with the magnetic moment per unit of mass, that is, per gramme.

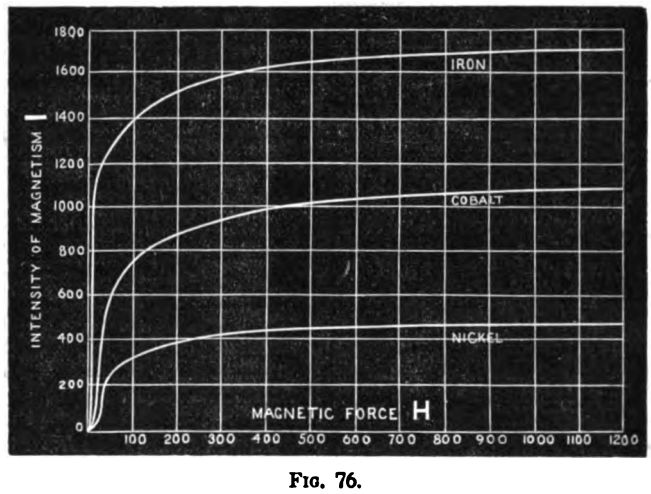

FIG. 76.

It will be more convenient for us to adhere to the usual practice of stating magnetisation by the quantity I, which is the moment per unit of volume, that is, per cubic centimetre. The results are accordingly reduced to this form in the curves of Fig. 76 and in table XXII., the numbers in which are calculated from measured values of the ordinates in Du Bois' curves.* The iron tested was soft Swedish wrought iron, carefully annealed.

TABLE XXII.—*Iron, Cobalt, and Nickel, in Moderately Strong Fields.*

Magnetic Force, H.	Intensity of Magnetism, I,		
	Iron at 0°C.	Cobalt at 100°C.	Nickel at 100°C.
100	1410	—	313
200	1520	856	375
300	1580	933	406
400	1627	988	428
500	1658	1018	441
600	1677	1032	450
700	1689	1048	456
800	1697	1056	459
1000	1705	1080	467
1200	1710	1090	471

The observations with cobalt and nickel were made at 100°C., but within the range of magnetic forces that is dealt with here the difference between 100°C. and atmospheric temperature has but little influence on the magnetisation.

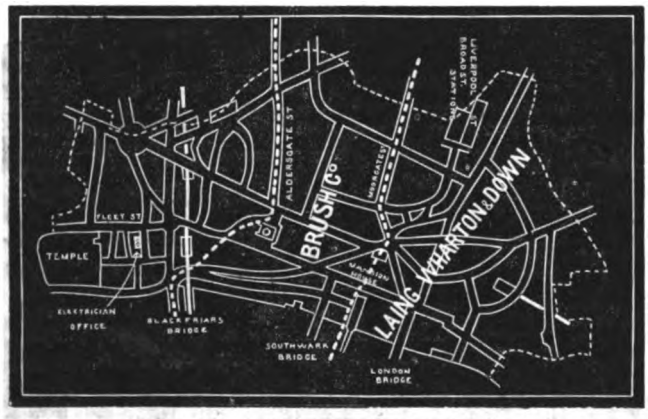
In Fig. 76 the same results are given, and the curves are completed to the origin (in an approximate fashion) by sketching in, from other data, the parts that relate to lower forces. The gradient of the cobalt curve at the upper end shows how cobalt needs a stronger field than the others to make its magnetisation approach closely to a state of saturation.

(To be continued.)

ELECTRIC LIGHTING OF THE CITY.

The Bill to confirm the Provisional Order for the lighting of the City came before the Unopposed Bill Committee of the House of Commons on Friday last, and was duly passed and confirmed. Under these Orders, the City is divided into three parts, according to the following map. The Laing, Wharton, and Down Construction Syndicate take the easterly portion, while the central portion is allotted to the Brush Electric Engineering Corporation. The Order differs from the Model Orders of the Board of Trade in containing a number of conditions which have been specially introduced by the City Authorities.



Map of the City of London. The heavy dotted lines indicate the boundaries of the three districts.

The streets throughout which the Brush Corporation have to lay mains within a period of 21 months are as follows :—

Barbican.
Beech-street.
Fore-street.
London Wall (west of Moorgate-street).
Gresham-street.
Upper Thames-street (west of Dowgate Hill).
Aldersgate-street.
St. Martin's-le-Grand.
St. Paul's Churchyard (south and east sides).
Wood-street.
King-street.
Cheapside.
Poultry.
Watling-street.
Cannon-street (west of Dowgate Hill).
Queen Victoria-street.
Queen-street.
Cripplegate-buildings.
Milk-street.
Aldermanbury.
Aldermanbury Postern.
Coleman-street.
Basinghall-street.

The streets through which the Laing Wharton and Down Construction Syndicate are to lay mains within 21 months are :—

Aldgate.
Aldgate High-street.
Arthur-street East.
Arthur-street West.
Bishopsgate-street Within.
Bishopsgate-street Without.
Cannon-street, east of Dowgate-hill.
Cornhill.
Eastcheap.
Fenchurch-street.
Finsbury-pavement.
Gracechurch-street.
Great Tower-street.
Houndsditch.
King William-street.
Leadenhall-street.
Liverpool-street.

The undertakers have to deposit a sum of one thousand pounds, to be repaid from time to time on certificate by an inspector of the Board of Trade. Besides the area shown on the map, the local authority, with the approval of the Board of Trade, may appoint to be included other streets or parts of streets within the City, the supply in these streets to be for public purposes only ; and the undertakers are to give such a supply of energy for the public lamps in the area of supply, and on such conditions, as may be for the time agreed upon between the undertakers and the local authority. Whenever the undertakers make default in supplying energy to the public lamps, they shall be liable to a penalty not exceeding forty shillings for each lamp, and for each day on which any such default occurs, provided that the penalties shall in no case exceed in the aggregate the sum of fifty pounds for any one day. No penalty shall be inflicted if the Court having cognizance of the case shall be of opinion that such default was caused by inevitable accident or *force majeure*, or was of so slight or unimportant a character as not to materially affect the value of the supply.

PATTEN'S IMPROVED MULTIPLEX TELEGRAPH.

The Patten multiplex telegraph, the following account of which is taken from a recent number of the *Electrical Engineer* of New York, bears a strong resemblance to the Delany system used by the Post Office. The details of the apparatus and the methods of synchronising are, however, different. The instruments are in use between New York and Philadelphia. This is a system of the synchronous multiplex type, depending for its operation upon the synchronous and uniform movement of two or more electric motors placed at distant points. In the present instance this is achieved by a novel application of the peculiar properties of electric motors, and the synchronism, far from being delicate, is powerful and reliable. The machine may evidently be of any size and power, and there is an evident tendency to run into synchronism instead of running out, which latter has been the case in former attempts at unison movements based upon the isochronous movement of a single machine. It is evident that an ordinary Siemens armature in a two-poled field must reverse its current at every half revolution. If by any means two such machines be caused to reverse their armature currents simultaneously, they would necessarily move in synchronism.

The apparatus used in the Patten system is simply an elaboration and practical application of this idea. Two electric motors at distant points are made to revolve in synchronism by causing the currents in the armature circuits to be simultaneously reversed through the agency of a controlling line current. The system will be understood from the illustration (Fig. 1), which is a diagram of all the operative circuits, including two terminal stations. The system is operated both as a single and a two-line system. In the two-line system a single synchronising line is used for controlling a movement of electric motors, and may be used to synchronise the motors for any number of lines. In the single-line system the synchronising current is used both for synchronising and telegraphing, without either function interfering with the operation of the other. For the sake of simplicity the two-line system is selected for description.

In Fig. 1, X and Y represent two terminal stations of a telegraph line. The synchronising line L L extends from the earth E^3 at X to E^4 at Y, reversing the polarised relays P^1 and P^2 at these stations. At any intermediate point in the line, whether at Y or X, or midway between, is placed a revolving pole changer, the function of which is to constantly reverse a current on this line derived from the synchronising battery 9. This pole changer is driven by an electric motor having independent field and armature circuits, by which means its speed may be regulated and controlled ; it is shown in the middle of the diagram. The lamps 11 are in the armature circuit in multiple arc, and by turning them on or off, the speed of the pole changer may be varied, the field remaining of uniform intensity excited by the battery 10. This pole changer sends rapidly reversed currents continuously to line, and maintains the polarised relays at X and Y in constant and rapid vibration. They necessarily beat in synchronism and are reversed by every half revolution of the controlling motor. These alternations set the pace of as many machines as it may be desired to place in circuit. Very little current is used for this purpose, the battery line on a 100-mile circuit having only about 30 volts potential. The current is necessarily very weak, and the vibration of the polarised relays is delicate but constant.

The armatures of these polarised relays could not carry sufficient current through their contact points to drive motors of any size or power, because of their lack of power to prevent sticking and welding at the contact points that would be occasioned by the making and breaking of such currents. To overcome this difficulty they are caused to drive a powerful vibrator in the same way that a relay actuates a sounder, the vibrator being placed upon a local circuit of low tension, V^1 V^2, and this is given sufficient strength and a suitable form to both rapidly reverse and convey the heavy currents of the motor armatures. These vibrators are shown at V^2 in the diagram, which is sufficiently clear to explain their operative parts. The polarised relay as it vibrates to and fro places alternately one

Digitized by Google

side and the other of the vibrator in circuit, and its armature is rapidly and strongly pulled first against one contact point and then the other.

8 amperes at 16 volts, the pressure is sufficient to cause a heavy spark and flame at the breaking of such a current and to weld the armature to the vibrator points, and much time and labour was required

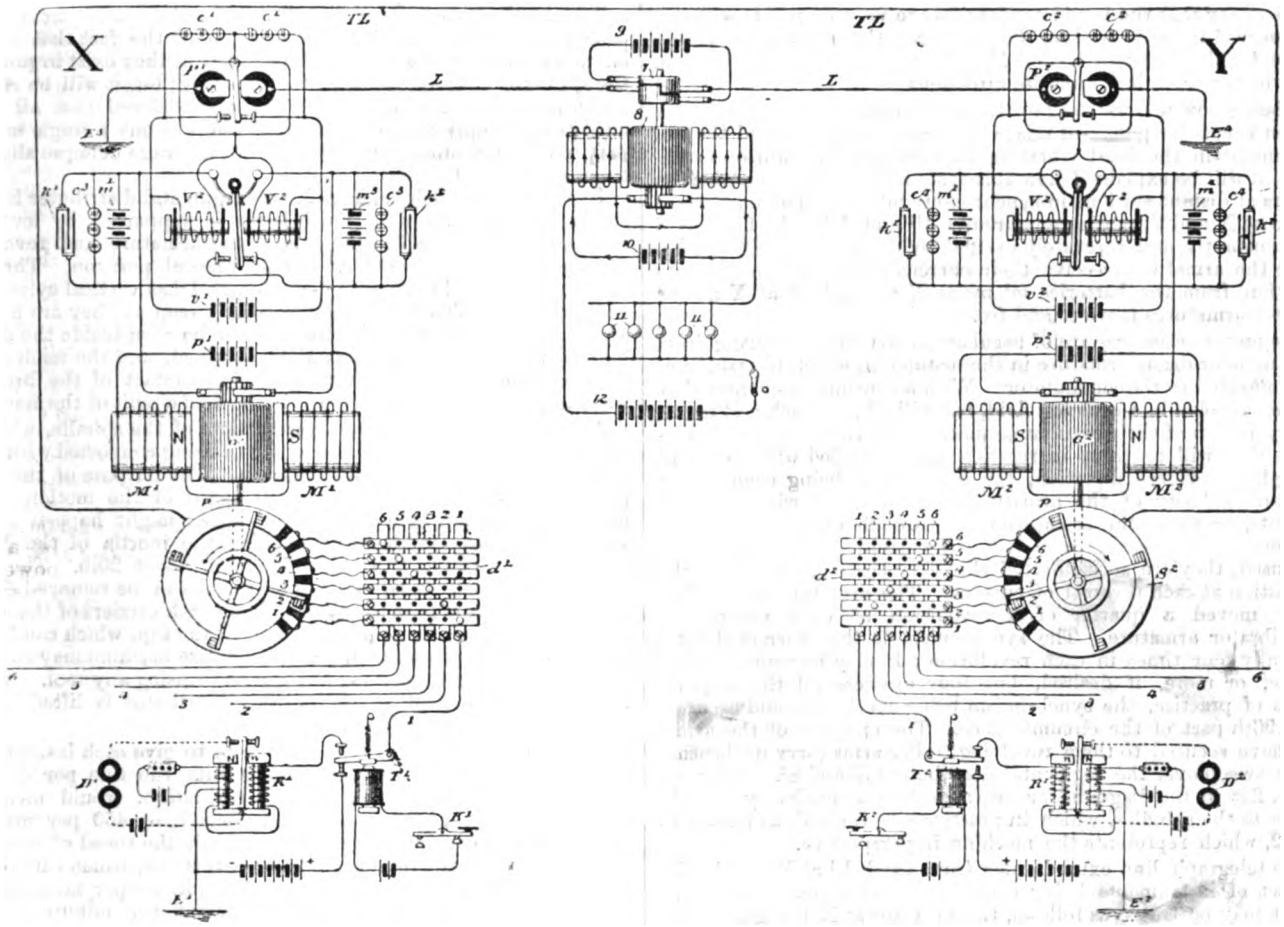


FIG. 1.—Diagram of Connections for Patten's Multiplex Telegraph.

The slight spark at the relay points is completely overcome by the liquid condensers C^2 placed as a shunt around these points.

to effectively overcome this difficulty. It may be said, however, that this current is now broken continuously at the rate of 800

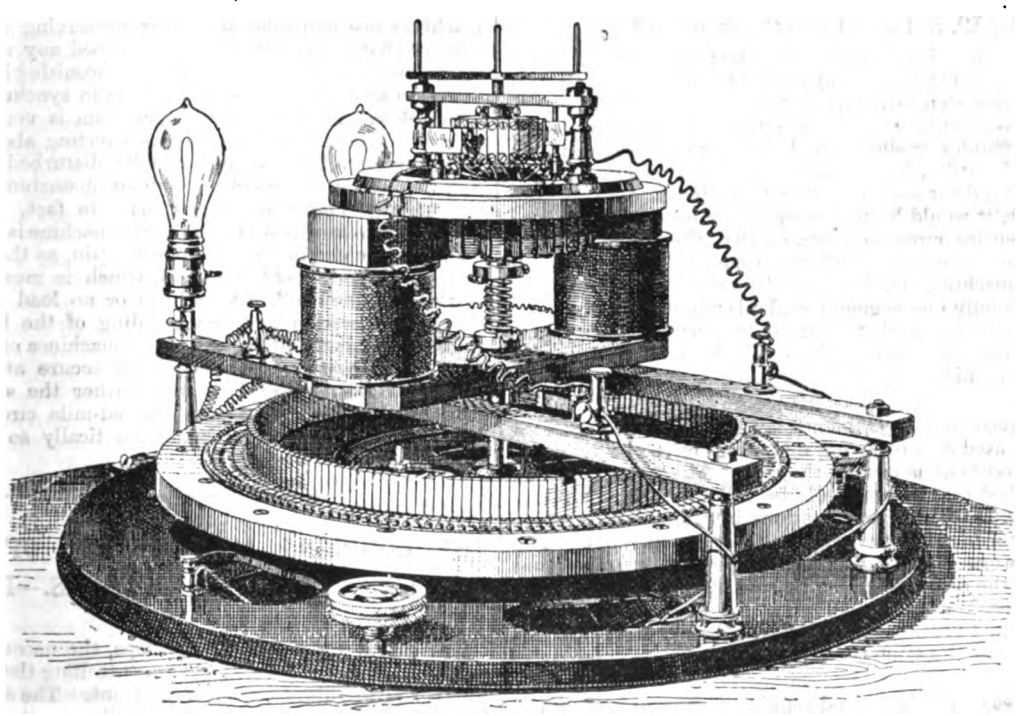

FIG. 2.—Patten's Multiplex Telegraph. General view.

With a small current this device is in every way sufficient to prevent any welding or sticking of the points. Not so, however, with the vibrator points. The armature current of the motors, being about

times a minute without producing a visible spark, and welding never occurs. This, which has been one of the greatest difficulties of the system, was effectually overcome by the system of devices

Digitized by Google

shown. These consist in a special arrangement of liquid and plate condensers placed in parallel as a shunt around the armature points. Neither of these will suffice alone, and only a proper and particular combination of the two will effectually kill the spark. This combination has been found as the result of experiment, and it will suffice to say that the liquid condensers are very large. It will also be observed from the system of circuits that there is always a closed circuit for the batteries M^2 and M^4, which are alternately placed in the armature circuit in opposite directions.

It being now understood how the regulator at some intermediate station keeps the polarised relays in unison movement, and they in turn maintain the local vibrators in corresponding unison movement, it will be explained how this system of devices maintains the motors at distant stations in synchronous rotation. The motors are shown at X and Y by diagram circuits M^1 and M^2; the fields N S are constantly and separately excited by the batteries P^1 and P^2, while the armatures receive their current alternately in opposite direction from the batteries m^1 m^3 at X and m^2 m^4 at Y as the vibrator armatures move to and fro.

The motor armatures are of peculiar construction, differing from a Gramme or drum armature in the manner in which the windings are connected to the commutator. With a continuous current they will not revolve in a constant field, but will vibrate back and forth; but by reason of their peculiar connections to the commutator segments they will continue in rotation when supplied with a current of rapidly reversed direction, the connections being such that a constant polarity of the armature is maintained with reversed currents, provided the armature turns through a certain arc of the circumference at each reversal of the current. As the system is now used, they are so connected that they move one-fourth of the revolution at each reversal of current. The armature is therefore really moved a quarter of a revolution at each reversal of the vibrator armature. The synchronism is thus corrected automatically four times in each revolution; it may be made eight or twelve, or more, if desired, but four answers all the requirements of practice, the synchronism being continuous and accurate to a 196th part of the circumference. The spindles of the armature have secured to them revolving trailer arms carrying brushes which sweep over the segmental distributors S^1 and S^3. They are shown flat in the diagram, for clearness, but are evidently at right angles to the spindles, which in practice are vertical, as shown in Fig. 2, which represents the machine in perspective.

The telegraph line extends also from earth E^1 at X to E^2 at Y, one set of instruments being shown in detail at each end. The circuit may be traced as follows, the operator at X being supposed to be sending, and the operator at Y receiving:—From earth, E^1, hrough the line battery positive to line, transmitter contact T^1, switch d^1, segment No. 1 of the distributer, and through the trailing brush to the large segment of the distributer, to which the line is connected; thence over the telegraph line T L to the large segment S^2, out through the switch d^2, transmitter back contact, receiving relay R^2, and completing the circuit at E^2.

Among the many novel features in the systems is first the fact that the distributer is not necessarily cut up throughout its circumference, as in other systems of multiplex telegraphy, and there may be only as many segments as there are circuits to be used on the line. Thus a sextuplex is shown, and there are six segments in the distributer. In order, however, to acquire a sufficient number of contacts per second for each operator to maintain a practically continuous circuit, it would be necessary to connect No. 1 to four segments in the entire circumference, so that this instrument as well as all the others would receive four impulses of current at each revolution of the machine. The same result is readily accomplished, however, by using only one segment and placing four trailers on the spindle, so that one is always in contact with the segment, while the other three are connected to line by contact with the uncut portion of the distributer. This greatly reduces the cost of such devices.

The system of receiving instruments is also decidedly novel; a polarised relay is used as a receiving relay, but it is not operated with reversed currents as is usually the case. The polarised relay is indeed so modified that it can hardly be called a polarised relay, properly speaking, as by the modifications introduced it is made responsive to intermittent positive or negative currents. The system shown is worked with intermittent positive currents, and is also worked on the open circuit or English system, the receiving relays being rendered operative by putting battery to line from the opposite end, and breaking being effected by opposing the two equal line batteries at the same time from the opposite ends of the line.

One complete set of receiving and sending apparatus is shown at each end. Of course those connected to the main circuit 2, 3, 4, 5 and 6, are identical with those shown connected to the circuit 1. They consist of a key, a transmitter, and a receiving relay normally of the polarised form, but modified as shown in the drawing by the introduction of an extra energising circuit around one core of the relay, this slight modification rendering the relay operative under the action of intermittent currents of one polarity or sign only. The sounder, D^1, by which the message is read, is operated in the usual way when the receiving relay is actuated by an incoming line current. A sextuplex is shown in the diagram, although excellent results have been obtained on a hundred-mile circuit when connected as a "twelveplex." By reason of the fact that all the circuits are shown in the diagram complete as they exist in practice, the system has the appearance of complexity; but it will be readily seen that it is not really so when it is considered that all these circuits are simply magnets, and that there is but a single moving part in each machine, the motion of the vibrators being so slight as to be scarcely noticeable.

In the motor machine, Fig. 2, the segmental distributer is near the base of the machine, which latter is supported by levelling screws by means of which the axis of the armature and revolving fly-wheel can be brought to a true vertical position. The distributor is about 15in. inside diameter, and has vertical cylindrical walls, against which the trailing brushes sweep as they are carried around by the heavy fly-wheel which can be seen inside the distributor. An interior contact is thus obtained, and the tendency is always to increase and preserve uniform contact of the brushes. The lamps are used as resistances in the field circuit of the machine.

A noticeable feature is the construction of the spindle, which is in two parts, the upper and lower halves being connected with each other by a spiral steel spring, as shown. The purpose of this is to prevent any sudden jerk or change of speed of the motion of the fly-wheel, although such a change of speed might happen to the armature; it also facilitates overcoming the inertia of the heavy fly-wheel at starting, this wheel weighing about 20lb. The base is open at the bottom so that the fly-wheel can be removed downwards through a hole in the table. The brush carriers of the armature rest in a similar circular frame at the top, which can be removed by lifting it out of place. The entire machine may thus be dismantled without removing any screws or using any tool. When the fly-wheel has been taken out the distributor is lifted off its carriage and slid out sidewise.

The speed is so regulated in practice as to give each instrument, when its circuit is closed, 30 contacts with the line per second, which, admitting four contacts per revolution, would mean an average speed of $7\frac{1}{2}$ revolutions per second, or 450 per minute. But as the distributor motors move at half the speed of the controlling motor in the middle of the line, this one, which carries the pole changer, is driven at about 900 revolutions per minute, producing therefore 1,800 reversals of current per minute on the synchronising line, and a corresponding number of vibrations of the polarised relay armatures. But as four of these are required to produce a single revolution in the armatures in the distributer motors, their speed is brought to about 450, as stated.

One peculiarity will be observed, namely, that this is not a terminal system as is necessarily the case where isochronous machines are depended upon for preserving synchronism. It is evident that in the system here described any number of polarised relays might be connected in the synchronising line, and they would maintain as many distributing motors in synchronism. The movement of the machines and synchronism is very decided as would naturally be expected, the motors exerting about one-eighth of a horse-power. The machines may be disturbed and lifted off their base and allowed to drop, without disturbing the synchronous movement. The trailer arms may, in fact, be struck, and the synchronism disturbed, but unless the machine is completely stopped, it will soon come into synchronism again, as there is a tendency to automatically correct the motion, which is measured by the power of the machine itself, having little or no load to carry other than that due to friction and the grinding of the brushes against the walls of the distributer. By using machines of such power, however, these contacts are made very secure and reliable. Under ordinary conditions of line and weather the system will work at "twelveplex" on a good one-hundred-mile circuit with reliability and decision, the circuits being practically so many independent lines.

THE COUPLING AND CONTROL OF DYNAMOS IN CENTRAL STATIONS.—I.*

As central station work develops, the necessity for considering the best ways of governing or controlling the pressure of a large number of machines comes to the front. The subject has not yet been dealt with systematically. In direct current work, low pressure of 100 volts or so, is universally used, except in series arc lighting and distribution from batteries used as transformers, which are outside the scope of this article. Even parallel supply from

* Abstract of an article by Mr. James Swinburne in *Industries*, Aug. 15th.

Digitized by Google

batteries and dynamos together will hardly be touched, as the pressure in the supply circuits then depends on the batteries, and is regulated by cutting cells in or out, and is not controlled by the dynamos, engines, or their regulating gear or governors. The three, four, or five wire arrangements are practically multiples of a single parallel system, and do not need special attention.

Direct-current station dynamos are always shunt-wound or separately excited. By separately excited it is not here meant that they have special exciters, but that the supply is taken from the mains. In this sense a dynamo running in parallel with a number of other machines may be regarded indifferently as shunt-wound or separately excited; and, as a matter of fact, the field-magnet circuit is always made before the armature circuit to ensure that the machine starts in the right direction. A number of shunt machines may be coupled together and regulated in various ways. In some cases each engine drives several dynamos, in others only one machine. Then the dynamos may have adjustable resistances in their field circuits, so that one field is altered at a time; or the whole of the field-magnet circuits may be arranged to be controlled together. Sometimes they are so arranged that each dynamo can be regulated by itself, and the whole of them can also be weakened or strengthened together as the load on the station falls or increases.

Take first the case in which each engine has a speed governor. Governors for engines are in the market in endless variety, and though great trouble and ingenuity have been spent, it is questionable whether mechanical governors have been studied from quite the right point of view. In the first place an engineer, in designing a governor, is far too apt to consider it by itself without taking the engine into account at all. This gives rise to several troubles. Many governors have been designed so as to be sensitive, and perhaps to be nearly isochronous when disconnected, but are then rendered quite useless by hanging on a heavy expansion link, or by setting the governor to work a stiff throttle valve or other gear. This is the commonest mistake of all in governor design. There is another more complicated question, which is of vital importance, and, so far as I know, has been little studied, and that is the question of "hunting."

Suppose an engine has a governor which, so far from being burdened with expansion links or gear, controls the trip gear of an engine on the Corliss principle. Suppose, instead of being perfectly isochronous, it is set to allow the engine to go 5 per cent. faster at no load. This governor may be arranged to respond to a variation of speed almost instantly, or it may have considerable inertia, or be provided with a dash-pot to make it respond slowly. Suppose, for example, that it responds fairly quickly. The engine has also a rate of response relatively to the governor. If the engine has a heavy fly wheel, and if it runs slowly, so that a cylinder full of steam represents a large instalment of energy, it will respond slowly to the governor, especially if the load is light. If, for instance, half the full load is taken off suddenly, the speed of the engine gradually increases, and the governor then commences to cut off the steam. The engine goes on increasing in speed as long as it gets more than half steam. We may suppose, for example, that the full-load speed of the engine is 100 revolutions per minute, and the no-load speed 105. At half load, the equilibrium speed should be 102·5. But as the governor does not respond instantly to the change of speed, by the time the governor has cut the steam down to half, the engine has quickened up to, say, 110 revolutions. The engine begins to slow down from that instant; but as the speed is above the governor's normal speed for half steam, the governor goes on reducing the steam. By the time the engine is down to 102·5 revolutions the governor has cut off far too much steam. It begins to increase the steam again, but the engine goes on slowing down till the governor gives it half steam. The engine then begins to quicken, but when it has got to 102·5 the governor has overshot its mark, and is giving too much steam. The engine then races again, and this cycle of things is repeated. It depends on the speeds of response of the governor and engine whether the hunting increases till the governor gives from no steam to full steam, in waves, or tapers off to a state of equilibrium—that is to say, of regular running. The speed of response of the engine varies with the load. An engine with a heavy fly-wheel and a light load will often hunt, and will run steadily when the load is put on. The hunting can be avoided by making the engine respond quicker, or the governor slower, or much quicker. The more nearly isochronous the governor is, the more tendency there is to hunting; and to avoid hunting it must then be made anisochronous, and it must respond very slowly. If it responds very slowly the engine may race on load being removed, or may slow down excessively on load being put on, the governor taking a long time to get to the proper position. This is, of course, very bad. Instead of making the governor respond slowly, the engine may be made to respond quickly. A heavy fly-wheel secures evenness from stroke to stroke of the piston, but it makes it difficult to govern as to average speed, for it makes the engine respond more slowly. Probably most of the difficulties in governing mill engines arise from the use of slow engines with big fly-wheels. On the other hand, a small high-speed engine is more easily governed. Even an engine like Willans', with a Willans governor, will hunt on light loads, unless the vibration period of the governor is made large. I have tried the same governor on a slower fly-wheel engine, and it was impossible to govern under one-third load. More recently I have made an electric relay governor to control an engine with an absurdly large inertia in proportion to its load, so that it responded to the governor very slowly. In this case the promptness of the governor could be reduced to any degree of slowness, and to get the whole into stable equilibrium the governor had to be made so slow that the period of the whole system was about fifty seconds. Even then, after a sudden change of load there was considerable hunting before the engine remained at its correct speed. In the case of electric lighting from stations, the tendency to hunt is often checked. In the first place, several engines and dynamos work in parallel, so that, unless they all hunt together, the proportion of load taken by each varies enormously with small changes of speed, and checks the tendency to hunt. Secondary batteries have also a similar effect. In the examples it was assumed that the load was independent of the variations in speed; strictly speaking, this is, of course, not the case. The variation of load with the speed, of course, also tends to check hunting—that is to say, it makes the engine respond to the governor quicker. The question of hunting is, therefore, not so important in direct current work, where many engines and machines are coupled together, as in alternating work, where one engine and one dynamo work one circuit. It is also important where one large engine drives many direct current dynamos not coupled to those driven by other engines. It is, therefore, worth while to go into the matter to some extent now, so as to avoid the necessity of returning to the subject of engine governors when I come to alternating current work.

So far, the governors have been supposed to be mechanical speed governors; electrical governors, of course, follow much the same laws. Dismissing all questions of hunting, the electrical government of a number of engines and dynamos, or, as they may be called for shortness, steam-dynamos, is very complicated. Take first the cases of a governor on each engine. If each is simply a pressure governor, it is controlled only by the station pressure, and the movement of the governor is not specially dependant on the doings of the particular dynamo it controls. The least inaccuracy in adjustment allows one dynamo to do more work than another. The governors only keep the pressure right as a whole, they do not know what share each dynamo gives. At first sight it would seem that an additional wire on each governor coil in series with the dynamo controlled by it would work, so that as soon as a dynamo gave more than its share of current its governor would shut off steam more than the others. This would, however, give a lower pressure throughout the station as the total load increases, for with the same pressure the ampere turns on each of the governors would increase with the load. The ampere-turns on the governor should remain constant, or if anything decrease, so that the station as a whole "compounds up" a little to compensate for losses in leads and feeders. To secure this some demagnetising current turns must be added to each governor, which are in series with, or proportional to, the current of the whole station. By making these slightly excessive compounding up of the whole station is secured. A new difficulty crops up, however. The demagnetising turns can only be permanently correctly proportioned if the number of steam-dynamos in use is constant, so that each always does the same share of whatever the output of the station may be. To avoid this difficulty means adding more complications to a system which is already almost too complicated to be of any practical value.

Instead of putting an electrical pressure governor on each engine, one may be put on the whole steam supply, or may be arranged to control all the engines by altering the ratios of expansion or otherwise. This arrangement has many advantages. An accurate governor that can be thoroughly depended upon is necessarily costly. It is much better, then, to put all the work into one thoroughly good piece of apparatus. Each engine can then have a speed governor set for twenty per cent. or so over normal speed, so as to prevent accident in case of a fuse going, or field circuit being opened from any cause. At light loads, if all the engines are on, of course the diagrams are bad, but an attendant shuts off steam from some and stops them, so that those running have fair loads. The stop valves are always full open or closed, the speed depending entirely on the main throttle valve. Instead of a main throttle valve, which is not always possible, owing to multiplicity of boilers, the expansion gear or cut-off or throttle on each engine may be controlled by the main governor. The action is radically different from that of an electric governor on each engine, for all the cut-offs or throttles are worked simultaneously and equally, so that there is no possible inequality of load among the dynamos.

(To be continued.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 5 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

NOMENCLATURE AS AN ART.

In a recent Paper by a well-known professor at a colonial university the mechanical properties of quartz threads were discussed, and one of these is treated under the title of "Nachwirkung." There is nothing in the communication to inform the reader as to the signification of the term, other than that which may be inferred from the paragraphs which deal with it. As descriptive of some kind of rigidity or strength, it might be expected that the word would be found in text-books of mechanical science; but it is unknown there. The obvious translation "after-effect" might mean elastic fatigue, to which part of the Paper is devoted, or half-a-dozen other well-known physical characteristics. A study of the context will suggest that the German word may be translated yet more literally as "back-working." But why all this trouble and vagueness? The true use of words is to represent ideas; and whatever the professional politician may think, the man of science should carefully keep this use in view when he has to make an addition to our vocabulary. With the progress of science, new ideas spring into existence, and if they are worthy of discussion, they must be designated by some name; but the choice is a responsible matter. The sponsors to the phonograph, microphone, telephone, &c., have perhaps produced as graceful results as might be expected from the dead languages employed. We certainly prefer "telescope" and "telephone" to the "fernrohr" (far-tube) and "fernsprecher" (far-speaker) officially used in Germany. "Nachwirkung" is a ready made word, while "back-working" is too clumsy for a moment's consideration. If the term "creep" will not do—and we see no reason why it should not—the word "anherpēsis," creeping backwards, from ἀνά and ἕρπω, might be formed on the model of hysteresis, or the existing word "anachorēsis," a marching back, might be employed.

Prof. TYNDALL, in writing on acoustics, uses the ugly word "clang" to denote the admixture of sounds existent in a complex musical "tone." He had the English words "tone" and "note" available, but accepted neither for the purpose. Moreover, he found no word by which to translate "klangfarbe," and discussed the merits of "clang" and "timbre," finally adopting the latter. But why introduce a foreign word, when "quality" is, for this purpose, a perfectly satisfactory expression? The French, it is true, are introducing English words almost daily into their technical literature. There seems to be a great poverty in the engineering and electrical portions of their vocabulary, and a reluctance to put together words to express the new ideas which are imported from other nations. The expressions "short-circuit," "shunt," "self-induction," "extra-courant," "switch," "torque," and others are examples. The Italian Government prefer to use the French language in diplomatic despatches, because it is conveniently capable of bearing so many different interpretations; and English for telegraphic purposes, because it is so economically concise in the absence of useless little particles, and because the meaning is perfectly definite. The flexibility of the English language for word-coining purposes is chiefly due to our habit of borrowing terms for use in one subject from the vocabulary of another. "Shunt" and "switch" are derived from railway practice. Their etymology is obscure; and, like many other colloquial technicalities, they are probably the wreck of other and less convenient names. In creating new terms we have a happy knack of using monosyllables, and we do not often build up compound words with a German disregard for euphony.

An article in the *Spectator* recently pointed out that it is better to wait until "the man in the street" finds a word for a new idea than to hastily manufacture such expressions as those which were proposed for expressing locomotion by electricity. The law of supply and demand must be obeyed in terminology as well as in dock strikes. It is useless to attempt to force the evolution of nomenclature. The neat name for the unit of conductivity, reciprocal of the ohm—the mho—has never "caught on," merely because the decimal system of notation is so much more popular than the binary system, and it is more easy to add resistances and find their reciprocals than to work with mhos. On the other hand, Sir WILLIAM SIEMENS suggested the watt at exactly the right time; it supplied the want which was just beginning to be felt, but which had not been expressed. The suggestion was received with applause, and the name was instantly absorbed into the vocabulary of electrical science. If "the man in the street" does not do his duty, there is a danger that some pseudologist may rashly give a nickname to the newest novelty. It is a mere coincidence that both "ammeter" and "secohm" are two of the most unhappy names we have. An ammeter is no meter, and an "am"—what is it? The instrument is a current gauge, and should have been so called. An attempt has been made to introduce this sensible name, but it is to be feared that "ammeter" has taken too firm a root. "Secohm" offends the ear, while it tells no tale. The "quadrant" is worse—but on purely scientific grounds with which we are not dealing at present, but which are discussed by Dr. FLEMING in another column.

There is, to our ears, a horrid vulgarity about "E.M.F.," which is the less excusable since the words for which it is the slang are themselves so inaccurate. Happily, there is but seldom any difficulty in substituting "pressure" or "volts" for that which is probably not electromotive, and which certainly is not force. Some purists think that "pressure" is a non-electrical word, borrowed, for want of a better, from mechanical science; but why so, more than "tension," which has been used and misused by the highest authorities? Tension used to be applied more frequently in cases where there was a great difference of potential, probably on account of a vague idea that there was a strain somewhere. If there be a strain, it is in the dielectric, not in the conductor. If Mr. FERRANTI has to deal with high tensions, they are those which exist *in* his insulating materials, not *at* his terminals. We like "pressure"; it is sufficiently accurate, and has the advantage of conveying a not erroneous meaning to the public. We cannot venture to guide the word-coiner in the art of supplying graceful additions to our terminology; but we have tried to point out some considerations which he would do well to observe; bearing in mind BACON'S remark—"And herein I cannot a little marvel at the philosopher ARISTOTLE, that did proceed in such a spirit of difference and contradiction towards all antiquity; undertaking . . . to frame new words of science at pleasure . . . wherein for glory and drawing followers and disciples he took the right course."

In conclusion we would note that there are in electrical engineering some curious coincidences between the names of inventors and mechanical appliances which have given rise to absurd mistakes. It was commonly supposed, some years ago, that the Brush machine was so called on account of some special kind of brushes. The Lever arc lamp, obviously because there were two peculiar levers in its mechanism. The Ball dynamo has no spherical armature, as might be supposed; the Short electric railway system is not specially adapted for lines of limited length. Bright shackles are never polished; and the Siemens' galvanometer has nothing to do with the mariners' compass, with which beginners sometimes confound it. The Parsons engine is not a clerical device; and the Upward battery has nothing in common with Excelsior carbons. Such popular errors may be excused, however, when we find a recognised text-book explaining the Daniell's cell as being so called because of its constancy!

THE LIGHTING OF LONDON THEATRES BY ELECTRICITY.

BY ED. C. DE SEGUNDO, A.M.I.C.E.

(Concluded from page 341.)

The Lyric Theatre (continued).—The following figures, showing the total cost of maintenance of the theatre, will, no doubt, be interesting to many, and—it must be remembered—they are taken from actual accounts paid from February 1, 1889, to January 31, 1890.

I give the exact figures supplied to me by Mr. Lyon:—

Maintenance of engines and dynamos, including wages of drivers, &c.	£507	10	7
Maintenance of accumulators	144	17	2
Gas consumed in engines, 6,854,000 cubic feet, at 2s. 6d.	858	0	0
Depreciation—			
Engines, at 10 per cent.	64	10	0
Belts, at 10 per cent.	5	0	0
Dynamos, at 10 per cent.	31	4	0
Accumulators, at 20 per cent.	460	0	0
Switch board, at 2½ per cent.	5	4	6
Wages: House and stage	277	4	5
Renewals, repairs, &c.	98	10	0
Cleaning lamps	5	19	9
Wages—Stage hands for performance	282	5	2
Carbons for arc lamps on stage and in front of house	15	5	6
Depreciation on plant in house and stage 5 per cent.	100	0	0
Superintendence	150	0	0
	£3,005	11	1

Digitized by Google

The number of watts consumed in the lamps and leads outside the switch room was 93,188,000. Thus, had the light been supplied by a public Supply Company the cost would have been as follows:—

93,188 units at 7d.	£2,717	19	8
Stage hands would remain the same	282	5	2
House and stage	381	14	2
Switch room	100	0	0
Depreciation on £2,000 at five per cent.	100	0	0
Superintendence	150	0	0
	£3,731	19	0

And if the theatre were lighted by gas the estimated cost would be as follows:—

Assuming a 5ft. burner = a 16 candle-power lamp (this is a very liberal assumption in favour of gas) and estimating that 2,458 gas jets would be required to give the same effect as is now produced by the electric light, we have 2,458 5ft. burners burning five hours a day consume 61,450 cubic feet per day at 2s. 6d. = per year	£2,386	8	2
One gas man	130	0	0
Renewals, repairs, &c.	150	0	0
Two cleaners at 30s.	150	0	0
12 lime light men at 3s. each	590	0	0
Gas mains used for stage	142	6	0
Extra cleaning	25	0	0
Depreciation on plant in house and stage	100	0	0
Superintendence	150	0	0
	£3,823	14	2

Provided there has been no slip in Mr. Henry Lyon's estimates and no misunderstanding on my part, we find the exceedingly interesting result that the cost of lighting a large theatre entirely by gas or by electricity supplied by a public company is pretty much the same; whereas a considerable saving is effected by producing the necessary electrical energy on the premises. But, of course, the interest on the first cost, as well as a portion written off the saving to form a sinking fund, should be taken into account. In this particular case interest at 5 per cent. on the first cost would alone bring the cost of maintenance above either gas or electricity supplied by a public company. But it should also be remembered that the cost of the plant for this theatre was abnormally high. It is probable that had the installation been carried out with due regard to economy, the cost of maintenance, including interest, &c., would compare favourably with the cost of either gas or electricity supplied by a public company.

The Court Theatre.—This installation was designed and erected by Messrs. Sharp and Kent, of 34, Victoria-street, S.W. It is a remarkable instance of *multum in parvo*, for the complete steam generating plant, together with all necessary accessories and fittings, are contained in a space 20ft. long, 12ft. broad at one end, and 8ft. 6in. broad at the other, and about 8ft. high. The plant consisted of two return-tube single-ended marine boilers, with separate uptakes into a common chimney, working at from 120lb. to 130lb. per square inch; a double tandem compound Willans engine, coupled direct to an 18 unit Goolden dynamo, and a 12 unit Parsons' turbo-generator.

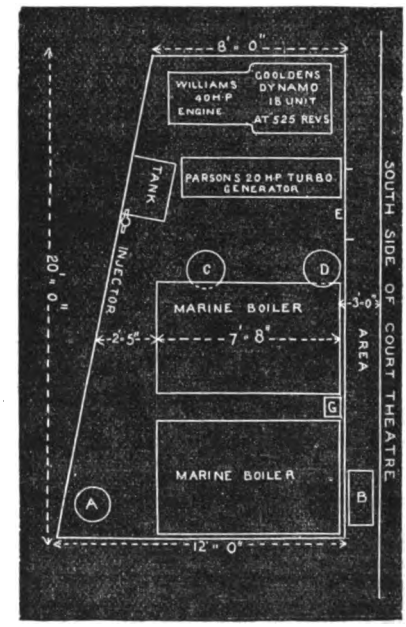
The feed is drawn from a tank and forced through a feed-water heater into the boilers by a donkey pump placed between the two boilers and arranged to communicate with either or both boilers. Each boiler is also fed by an injector. The steam passes through a separator from the boilers before entering the cylinders of the engine running at 525 revolutions per minute.

After the plant was erected and running, the roadway was reinstated in iron work and concrete; the driver and stoker were then completely boxed in, the only access being by a ladder into an area and through a door 4ft. high: a coal shoot at the far end admitted some little air; but daylight was quite absent.

The steam and exhaust pipes are all of copper.

It will not, of course, for an instant be supposed that the electric lighting plant was placed in this position from choice, still it is only fair to Messrs. Sharp and Kent to state the reasons which restricted the available area to so small an amount. The reasons are briefly these:—It had been intended to supply the theatre by electricity from the mains of a public electric supply company. As, however, the Company in question did not make satisfactory progress in the matter of laying mains, it was decided, two months before the opening of the theatre, to put down generating plant on the premises. Then it was discovered that as no space had been allotted for this purpose, and as no space could be spared, the only way out of the difficulty was to excavate under the roadway, and place the machinery underground. Then it was found that the only available spot was bounded on one side by a main sewer, on the next by property belonging to the District Railway, on the third and fourth sides by theatre buildings; and thus Messrs. Sharp and Kent found themselves face to face with the problem how to place the steam and electrical plant in duplicate for about 350 eight candle-power lamps on 200 square feet by 8ft. high. It has been done, and, all things considered, has been eminently successful, for no complaints are made by the management as to the intensity of the light, nor are any serious mishaps reported.

From time to time the number of lights in the theatre has been increased, until for several months past the nightly output has been over 20 units, or double the amount for which the plant was originally put down. This throws considerable strain on machinery running in a temperature of 110° to 112° F., and exposed to coal and ash dust.



Plan of Engine-room at the Court Theatre. Scale, $\frac{1}{8}$-in. = 1 foot.

A, Coal shoot; B, Chimney shaft; C, Steam separator; D, Feed-water heater; E, Doorway, 4ft. 7in. high; G, Double-cylinder pump. Underground height, 8ft. 6in.

Small available space for machinery does not only call for considerable ingenuity on the part of the engineer as to the disposal of the various parts of the plant in the area at his disposal, but it implies difficulties in maintenance which it is not always easy to foresee. A problem of this description is by no means solved when all the machinery has been packed in its place, due regard must be had to facilitate access to working parts so that they can be exposed, if necessary, for inspection or repairs. Thus the test of an engineer is not merely that he has done what is required, but that the arrangement is such that future possible contingencies are as far as possible provided for, so that the plant may, with proper care and supervision, be made to work always at its proper efficiency. Messrs. Sharp and Kent have been very happy in their choice of boilers and engine, and the plant is fairly "get-atable" for cleaning and so forth.

It is especially worth recording that Messrs. Sharp and Kent only received the order to proceed two months before the opening of the theatre, that boilers, engines, and dynamos had to be manufactured specially to suit these unusual conditions, and that everything was done and the plant started within the specified time, namely, six weeks from the date of the order. Above is a sketch plan of the installation, which will give some idea of the difficulties encountered and overcome.

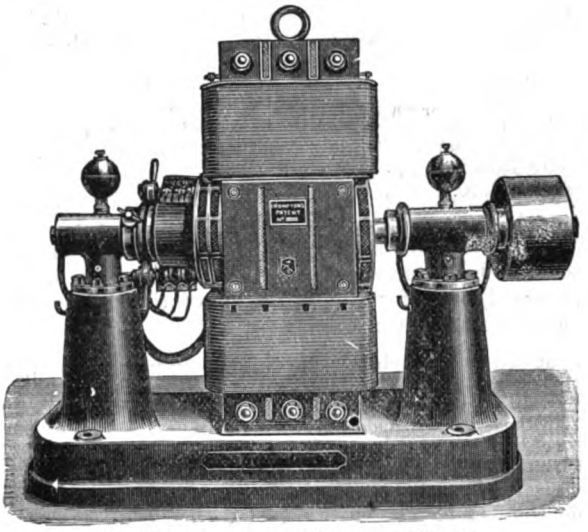
Digitized by Google

Covent Garden Theatre.—There is an interesting primary battery installation supplying the smoking lounge with light at this theatre. The batteries belong to the Weymersch Electric Battery Syndicate. There are 39 eight-candle power lamps in the lounge and the necessary plant consists of 16 six-cell batteries placed in the cellar. Quite recently the report of Messrs. Alabaster, Gatehouse and Co. appeared in the electrical journals, in which a full description of the battery and method of working was given, so that it is unnecessary to enter into such detail here. This installation is worth mentioning in that it is successful, practically and commercially. So many primary batteries have been taken up by influential syndicates and have all died natural deaths, that technical men may be forgiven for being sceptical on the question of the commercial possibility of electric lighting from primary batteries. There seems to be no doubt, however, from the figures contained in the report, that temporary electric lighting on a small scale can be produced more cheaply by this battery than by gas engines and dynamos.

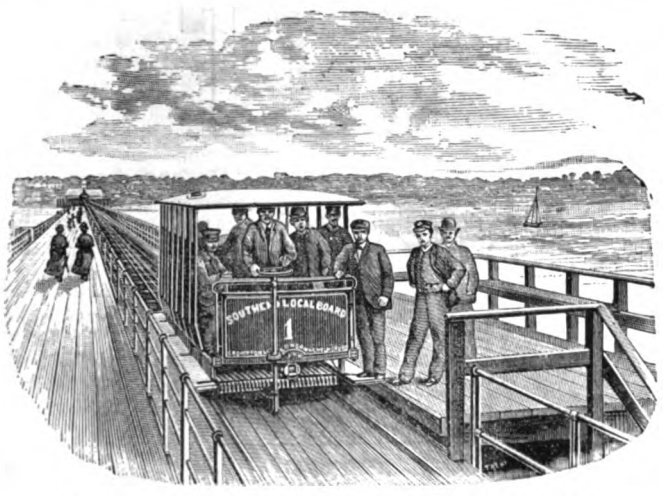
[The author might have taken into account the great saving effected by the absence of dirt and tarnishing of decorations in making his comparison. This alone, to say nothing of the less calculable advantages of coolness and reduced fire risk, enables the cost of the plant for a theatre to be paid for in a few years. —Ed. *E*]

THE SOUTHEND ELECTRICAL TRAMWAY.

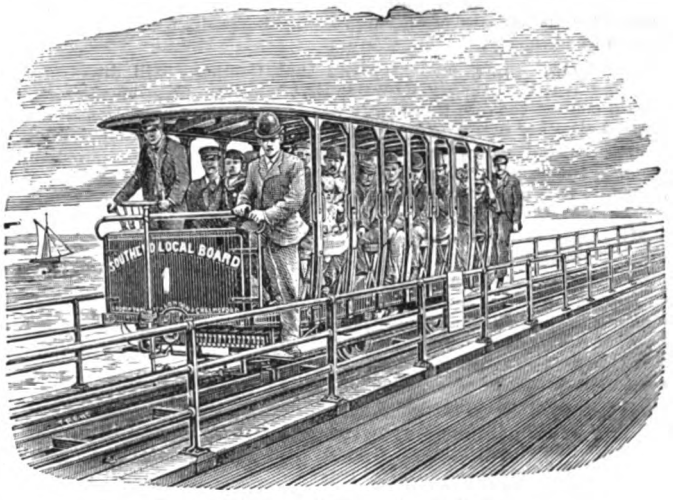
The interesting features of this tramway are the despatch with which the work was carried out, and the means by which this was accomplished, by using material from stock. The Southend Local Board, which is following the example of the enterprise of other watering places in spending money on local improvements, recently replaced the long wooden pier by an iron structure, at a cost of about £80,000. To keep things up to date, it was decided to furnish the new pier with an electrical tramway. Tenders were invited, and the contract was secured by Messrs. Crompton and Co. Three-quarters of a mile of track was laid the car built and fitted; a horizontal compound engine by Davey Paxman, with a boiler of locomotive type, was provided, and the connecting cables were laid so smartly that the tramway was at work in six weeks, and succeeded in earning on Bank Holiday the satisfactory "traffic receipts" which we mentioned last week. The dynamo is of the Crompton standard type, and is compound-wound for 150 amperes at 200 volts. The conductor on the pier is of the ordinary 1in. by ·134in. copper strip, which is used for street mains; and the supports, insulators, and straining gear have been taken from stock, and are identical with those used in 30 miles of streets in Kensington, Belgravia, and Notting Hill. The insulators are placed at intervals of 15 yards, and straining gear with volute springs are placed at every 85 yards. The track is of 3ft. 6in. gauge, the rails being of Vignolle's type. The conductor is laid about 12in. from one of the rails, and 1in. below the level of the rail tops. The rails are used for the return. The motor is a stock pattern; it is speeded down by simple spur gearing as 3 to 1. At both ends of the car are handles for starting and reversing, with an ordinary brake. While 20 miles an hour can be attained, the car runs generally at 12 to 14 miles an hour, the trip being made in three or four minutes, instead of 15 minutes with horse cars. The current is collected by rubbing contacts designed by Mr. Chamen, to whom, with Mr. Scott Moncrieff, special credit is due for the prompt execution of the work. Dr. Hopkinson, as consulting engineer to the Local Board, expressed great satisfaction with the work, which is much appreciated by the residents. The power required for propelling the car is considerably below that which was expected; and Messrs. Crompton and Co. hope to make measurements of the tractive force, and intend to publish the results of their experiments.



Crompton Dynamo; 150 amperes, 200 volts.



End View of Car, three-quarters of a mile down the pier.



Car travelling at sixteen miles an hour.

THE LANE FOX PATENTS.

We have received the following from Mr. Erskine, the hon. sec. of the Defence Association, whose offices are at 148, Brompton Road, London, S.W.:—

TO THE EDITOR OF THE ELECTRICIAN.

I enclose a circular letter which I have sent round to a large number of firms interested in electric lighting, and I should be greatly obliged if you could find space for it in your next issue, as it will then reach some interested with whom I have been unable to communicate.

Digitized by Google

THE LANE FOX CLAIMS.

SIR: In further reference to the above, a meeting was held on the 13th inst., at which several of the principal members of firms and others engaged in electrical engineering were present, and it was resolved to form an association for mutual defence against the Lane Fox claims. At this meeting ten firms signified their adherence.

You will see at once from the fact that the above number of firms have agreed to join the Association, that the Association has already received large and influential support; but it was the general opinion that all those interested in the matter should be allowed the opportunity of joining the Association on the original basis as proposed in my circular letter of the 22nd July. I was, therefore, instructed to ask you to let me have your definite reply on this matter not later than the 30th August.

In naming a date for your adherence, I beg to call your attention to the fact that we are on the eve of various attacks on the electrical trade in the shape of attempted monopolies, and that it is of the greatest importance that it should be at once seen that the *whole* trade are alive to this, and are prepared to resist immediately any unfair interference with the progress of the electric light industry.

August 15, 1890.

In reference to this matter, the following letter was sent out on the 22nd July last, accompanied by the circular setting out the proposed basis for the formation of the Defence Association, which is also given below:—

Your attention has perhaps been called to certain claims which have recently been put forward by the Lane Fox Electrical Company (Limited), with regard to the system of distribution by means of secondary batteries in conjunction with dynamos. The Lane Fox Company claim the exclusive use of this system by virtue of the patents granted to Mr. Lane Fox in 1878, and they are demanding royalties accordingly.

Amongst others against whom the claim has been made is my Company, and my Directors have therefore caused the matter to be investigated, and have obtained an opinion from their technical and legal advisers as to the validity of the claim. The result has been to satisfy them that the claim cannot be sustained, and they therefore propose to resist it.

The case, however, is obviously one in which successful resistance on the part of any one defendant will enure for the benefit of all who are making use of the system; and it appears to my Directors that it would only be prudent and expedient that all concerned should co-operate in the defence. They have therefore instructed me to communicate with you, and with others whom they believe to be interested, with a view of forming an association for the purpose of offering combined opposition to the claims of the Lane Fox Company.

It is not yet known against whom that Company will direct its first attack, but it is obviously desirable that whoever may be thus selected should contest the case thoroughly so as to secure a decision which will protect all other users. The question interests alike the supplying Companies, the contractors who do electrical work, and the private individuals who use the system in their private installations, and it appears to my Directors that an opportunity of co-operation should be given to all concerned.

My Directors have already opened communication with several of the other Companies interested, and two or three of them, including amongst others the Westminster Electric Supply Corporation (Limited), and Messrs. Crompton and Co. (Limited) have promised to co-operate. Further, the opinions of Sir Frederick Bramwell, Mr. Swinburne, and Mr. Kapp have been obtained, all of whom agree in advising that the claims of the Lane Fox Company cannot be sustained. Those opinions have been submitted to counsel on behalf of my Company, and counsel's opinion is to the like effect. My Directors, therefore, feel justified in believing that the claims could be resisted successfully, and they think this could best be done by the formation of an Association upon some such basis as is indicated in the terms set out on the enclosed paper.

I am now instructed to ask whether you will be prepared to join such an Association. You will observe that it would not commit you to a larger expense than £... unless after consideration of the matter in general meeting you should be willing to carry your liability further.

Probably it will be found convenient, if a satisfactory number of adhesions should be received, to form a small Committee to represent the Association and direct any proceedings which may be taken for the common benefit, it being always understood that neither the Committee nor the Association itself should have the power to compel the continuance in the Association of any member who desired to withdraw or to impose upon such member any pecuniary responsibility beyond that which the member might actually have agreed to undertake.

My Directors would be willing to give the Association the use of this Company's office for the purpose of carrying on the work, so that no expense need be incurred except such as may be incidental to the employment of technical and legal advisers, and such printing and stationery as may be necessary.

It would be well to get the Association formed without delay, and if possible before the commencement of proceedings by the Lane Fox Electrical Company (Limited). I shall therefore be glad to be favoured with your views on the subject at your earliest convenience.—Yours faithfully,

R. S. ERSKINE, Secretary,
The Kensington and Knightsbridge Electric Lighting Company (Limited).

To.....

PROPOSED BASIS FOR THE FORMATION OF A DEFENCE ASSOCIATION.

An Association of Companies, Firms, and Persons using secondary batteries as accumulators of electrical energy in connection with the supply of current from dynamos, for the following objects:—

1. To defend any action that may be brought against any of them by the Lane Fox Electrical Company, who are threatening to commence actions in respect of the letters patent owned by them, and alleged to cover the system of supply above mentioned.

2. To take such advice, and collect such information, as may be necessary for the protection of the rights of the several members of the Association to use the system of supply above mentioned.

3. Supply companies to subscribe a minimum of £50, contractors £25, and owners of private installations £10, to be called up as required; this would entitle members, thus constituted, to claim that the Association should defend any action to the extent of the funds subscribed, and any additional amount which may, from time to time, be voted in general meeting, which might be brought against them by the Lane Fox Electrical Company, in connection with the above-named claims.

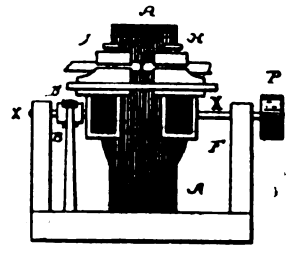
4. Should further funds be required, the members are to be called upon to subscribe in the ratio of the sums above mentioned, according to their respective denominations.

5. Any member of the Association may retire at any time, in which event this Association shall no longer be under any liability to defend any action which may have been brought, or may be brought against the member in question.

A NEW WELDING DYNAMO.*

The accompanying figures represent a new dynamo recently designed by Prof. Elihu Thomson. This machine was devised with a view of securing great compactness, and to enable the welding currents to be carried directly to the work without collecting brushes.

FIG. 1



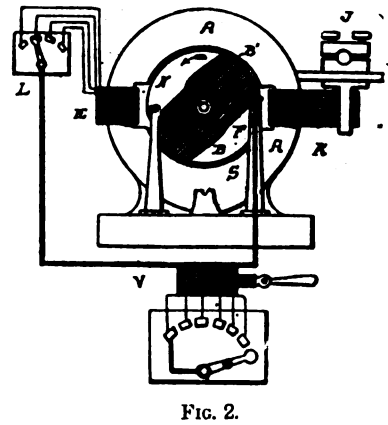


FIG. 2.

The chief feature of this generator consists in the employment of a revolving field-magnet, a stationary coil in which currents are developed by the revolution of the field-magnet for supplying the exciting current of the machine, a second stationary conductor in which the heavy welding currents are developed by the revolution of the field-magnet and a commutator on the shaft of the field-magnet for commuting the exciting currents before they reach the revolving field coils.

Regulation is secured, first, by governing the current supplied to the work by means of a coil of variable reaction or self-induction interposed in the circuit of the exciting current between the exciter supply-coil and the commutator, so as to be traversed by the alternating currents before they are commuted to pass through the revolving field-magnet as a straight or unidirectional current.

The general design of this machine is represented in the figures. Fig. 1 is a side elevation and Fig. 2 an end view of the generator.

* From the *Western Electrician*.

Digitized by Google

In the diagrams N S are the poles of the revolving field-magnet, resembling in form an armature of the Siemens shuttle type. A A is the iron of the armature, which is here represented as a laminated ring with spaces cut away for the exciter supply coil E and work supply conductor K. A commutator of two half circles with brushes B B′ has its segments connected, respectively, with the terminals of the field coil F. The brushes are connected respectively with the appropriate terminals of the exciting coil E. Interposed in the exciter circuit is a variable self-inductor V. The work supply conductor K terminates in two clamps J H for holding pieces of metal to be welded. The work-supply conductor K consists of one turn, or two or three turns around the armature core A A. The exciter supply coil E is wound in sections, and a switch L is used to vary the number of sections included in circuit for use. During operation the current, which is generated in E and excites the field, is varied by V, so as to control the potential and current of the work supply conductor K.

HIGH SPEED IN ENGINES FOR ELECTRIC LIGHTING.*

Although Watt was not "the inventor of the steam engine," as the great improver and introducer of the engine he deserves all the honour that later generations have accorded him. The invention of the details of the modern engine was sufficient to entitle him to all this, even had the machine done vastly less for the race than it has actually accomplished; but the benefit conferred was largely through the action of secondary and resultant developments.

Since the days of Watt there has been no industrial development even approximately as important as the now familiar and almost matter-of-course introduction and extension of the various applications of the power of steam through the intermediary of the electric current. The growth of steam engineering during the last decade or more has been almost as great and as wonderful as during the earlier days of the development of the Watt engine. The use of the electric light and of electric power transmission, as in the use of motors and on street railways, and the many minor applications of electricity have compelled the expansion of many old lines of business most remarkably, and have accomplished even more remarkable things in the institution of new kinds of production.

The maker of wire has been forced to seek the finest and purest copper, and to draw it into wire, harder, stronger, and in greater lengths, than it was ever before supposed possible to secure; new kinds of insulation, new systems of support and of preservation, have come into use, each improvement bringing after it a long train of minor or accessory inventions, discoveries, and improvements. Innumerable new forms of dynamo-electric machines, each specially and precisely adapted to a certain prescribed purpose, generators and motors of once unimagined perfection and efficiency; with, for each one of them, a host of little improvements and inventions in detail, have set the world agog with their work, have made the engineer wonder at their ingenuity, and have puzzled even the man of science and the professional electrician by the delicacy and subtlety of their theory, and by the variety and singular characteristics of their interacting currents and forces.

Finally, the steam engine itself has been given new forms to meet the requirements of this imperative new master. We propose briefly to consider the latest modifications of the engine, giving a concise and untechnical account of its special peculiarities, and the principles of its construction and application, as dictated by the new purposes to which it is sought to apply it.

There are two principal characteristics that distinguish the machinery employed for electrical distribution of energy from most other kinds of apparatus driven by the steam engine. The speed of rotation is unusually high, and the regularity of its motion, to insure satisfactory results, must be made extraordinarily perfect. To these two essentials all other considerations are subsidiary. In the various forms of machinery employed in the arts, outside this department, the first demand of the prime mover is generally economy of operation, and the exactness of its motion is a secondary, though often important desideratum. In the most exacting work, that of cotton machinery producing fine goods, it has been thought that the regulation of the engine driving it should be made sufficiently perfect to keep the fluctuation, with usual variations of loads, within about one per cent. of the mean, and within a total range of two per cent.; but, in electric lighting machinery, the range considered allowable is oftener half these figures, and some makers guarantee that the fluctuation shall be imperceptible, from full load to no load. The usual speed of the main line shafting in mills and in shops is rarely above 200 turns per minute, while, in the dynamo, the range is from about 1,000 on those of moderate size and of special types, up to 2,500 and 3,000 in extreme cases; while some are constructed to turn very much faster than the latter, even. The engine demanded of the trade for these latter purposes, therefore, must be capable of regulation to within perhaps one-half the range of the older types, and must be fitted to couple directly to machinery having five or ten times the speed of rotation of ordinary mill machinery. This demand, exacting as it is and seemingly impossible to meet, as it would have been thought not many years ago, has been satisfactorily fulfilled by a number of inventors and constructors.

The difficulties to be encountered in the attempts to comply with such conditions can hardly be realised by those unfamiliar with the steam engine and its development. It was at once evident that the speed of rotation must be increased, and the ideas of Charles T. Porter, who had, as early as 1860, shown that speed is an element of economy, and had begun to exploit a "high-speed" engine, seeking economy in that manner, were recognised as elements of the new form of engine. In the days of Watt, the speed of rotation had rarely, even with small engines, exceeded 50 revolutions per minute; and Mr. Corliss considered that a speed of 75 revolutions was about as high as his tripping mechanism would ordinarily allow; but Porter went up at once to 200, and the Corliss engine is now sometimes driven at over 100 revolutions per minute. The modern high-speed engine goes far above these figures, however, and 300 revolutions is thought a very fair, but not radical, limit. In a few cases, as in engines of Ericsson and others built for special applications, this speed has risen to as high as 1,000, and even, with very short strokes of piston, experimentally to over 2,000.

Some of the conditions of success in the attempt to solve this great problem are sufficiently evident. The obviously essential high speed of rotation of such engines can only be attained by simplifying the construction of the machine just as far as practicable, and by discarding the "trip cut-off" and adopting some "positive motion" valve gear. But the trip was considered the vital element in the regulating mechanism of the older engines, as it allowed the governor to do its work without introducing irregularities in its action through resistances coming from the valve motion. Porter adopted a "positive" and then secured good regulation by the use of the powerful loaded governor, in the form now so well known by his own name. Hartnell and Guthrie, the inventors of the device in England, and Hoadley, the first to use it in this country, by adopting the now almost universally employed "shaft governor," gave to all later makers the means of solving this problem most satisfactorily, enabling them to use the simplest possible valve gear and yet to obtain a good distribution of steam and the most perfect regulation at the same time—conditions formerly considered absolutely incompatible.

It is practicable to make the "detachable" valve gear operative up to speeds even exceeding 100 revolutions per minute; the shaft governor is adapted to velocities of 200 turns and upward; the higher the better. At 300 revolutions a minute, a common speed with this class of machine, it is possible to regulate, by nice adjustment, to within a range of one-half of 1 per cent. This has been attained in engines tested by the writer, and may be attained by careful manipulation of the best high-speed engines of almost any well-known makers. This solves the second of the prime requisites—the first from the point of view of application, perhaps—that of exact regulation. No system of electric lighting can be satisfactory in which the fluctuation of speed of engine can be observed at the lamp, in its varying intensity. Such fluctuation cannot be perceived where restricted to a fraction of 1 per cent., nor can it practically interfere with good work when kept well under 2 per cent., the once accepted limit.

Economy comes in as a third requirement of the new type of engine. The older "simple" engines were expected to give the horse-power on an expenditure of not more than three pounds of good coal per hour, if non-condensing, and about two pounds if condensing; which corresponded to about twenty-five or seven pounds of steam for the first, and perhaps twenty pounds for the second class, with the best modern boilers, economisers, and heaters. But the older types of engine had a great advantage in their admirable systems of valve-gearing, which gave an equally excellent steam distribution; the separate steam and exhaust valves, separated ports, and quick cut-off all conspiring to enable the engineer to secure the closest possible approximation to the perfect ideal which is essential to maximum efficiency. The use of a single valve, in the high-speed engine, restricts him very seriously, and compels a certain loss of efficiency. From 30 to 50 per cent. more steam was thus at first used in these engines. Good proportions of valve and of gearing, ample high speed of rotation—itself an element of economy—and practically frictionless and "isochronous" governors were brought out; but the machine still remained a less economical heat engine than the older type, and, in most instances, seriously so. The source of this waste and the methods of its prevention were promptly made the subjects of investigation, and the wonderful inventive faculty of the American engineer was set at work to devise improvements.

* Abstract from a Paper by Robert H. Thurston, Director of Sibley College, Cornell University, in the *Electrical World* of New York.

Digitized by Google

The cause of waste was very quickly detected in the large amount of "internal condensation" or "cylinder condensation," as it has come to be called, which was consequent upon the high heat-conducting power of the metal of which the cylinder is composed, and the exaggeration of this loss which comes from the increased proportion of surface exposed to weight of steam passed through the engine, as sizes are diminished. The increased speed of engine had diminished its size for a given power, and this had, in turn, with the less effective steam distribution, produced a large percentage of waste. The amount of this loss varies, in ordinary good practice, from about 25 or 30 per cent. in an engine of about 200 indicated horse-power, to 40 or 50 per cent. with engines of 50 horse-power of the same make, and to 60 or 70 per cent. in engines of from 1 to 5 horse-power. The remedies previously found effective in the prevention of waste were, however, well understood, and were promptly put into practice by the more enterprising builders. These are three in number: 1. Increasing the work of the engine in such manner that the amount of condensation in the unit of time being given, its proportion to the quantity of steam used in the engine in the same time should be reduced. 2. Superheating the steam, thus reducing its capacity for wasting heat in the engine. 3. Compounding the engine so that the waste of the one cylinder might be utilized in supplying the demand due to waste in the succeeding cylinder.

The first of these methods had been found effective, but the new engine was precluded from resort to this expedient from the fact that it was already constructed for as high speed as was found practically safe and satisfactory. The second device was known to be effective; but, while every builder endeavoured to secure dry steam, with more or less success and without meeting with serious embarrassment, the attempt to use superheated steam had been shown, by many years of experience, to be invariably attended with more or less risk to boilers and engines, and with considerably enhanced cost of maintenance. On the whole, superheating had never become a successful and accepted method of increasing economy, though well known to be in theory and in practice a most efficient means of reducing these internal wastes. A half century of experimental use, under all known conditions, had not given it permanent place among the standard expedients for securing maximum economy of steam and of fuel, even though endorsed by the highest of European authorities, M. Hirn. A few great designers and builders, as Corliss and Leavitt in this country, and Cowper and a few others in Great Britain and on the Continent of Europe, had, in special cases—usually in steam pumping engines—made good use of the device; but these instances were rare, and the system was, and is, but slowly gaining ground.

Compounding, on the other hand, had been practised from the days of Hornblower, the rival of Watt. At first entirely unsuccessful, the gradual rise of steam pressures, the gradual increase of the ratio of expansion, and the continually increasing demand for economy in use of fuel and of steam, gave this system a stronger hold as the years went by, and it at last became, a generation ago, a somewhat common method of construction of large engines for important work, and has now become the universal system in marine engineering and in some departments of stationary engine building, as in pumping engines and the finer class of mill engines of large power. It was not quite understood, however, until recently, by the average practitioner, what were the real causes of its efficiency, and it was not known whether it would pay to employ it in small engines. This last doubt was promptly removed upon trying it, and the "high-speed compound engine" is rapidly becoming the standard engine for its special field of work. It was found that the total gain in the best constructions, due to compounding, amounted to something like one-third on engines of large power, and often to one-half with the smaller sizes. This made the difference between success and failure in many cases, and with a handsome margin on the right side. Nearly all builders promptly took up the system, after the first experimenters had gone ahead.

So far as now known, there are but two ways in which further improvements can be effected. The speed is at a limit beyond which it is expected to go but slowly as methods of construction are improved, and as the attendants become accustomed to management of the new engine; the regulation is as near perfection in the best engines as is either desired or expected; and simplicity of construction can hardly be carried further; indeed, the symptoms are rather that we may see a reaction in the direction of a multivalve distribution in some cases.

The economical use of steam is still far from that indicated by theory as the ultimate. The engine above referred to demanding from 25 to 70 pounds of steam per horse-power per hour, as actually built in the various sizes specified, should, if the ideal conditions could be attained, give its power at the rate of less than 18 pounds. The best engines built to-day, of any type and of highest duty, have an ideal expenditure of about 8 or 9 pounds of steam per horse-power hour, while they actually employ from 13 pounds upwards. The two ways in which these losses, of a third or more, can be further reduced, so far as now known, are increasing the temperature, and, perhaps, the pressure of the steam used, and the production of a non-conducting and non-radiating surface within the cylinder of the engine.

Superheating the steam was shown by Hirn to be the best and most philosophical method, provided it could be made practicable from the constructor's point of view. This has not yet been generally practised, but it is not improbable that it may be done with good design and construction of the superheating apparatus and proper management of the engine. Its use would render the jacket superfluous, as it is known that the latter has no appreciable effect where the steam is kept dry in the cylinder. No wastes are left that it can affect. It would substitute for the disadvantages of the jacket, as a matter of construction, those of the superheating system. The latter have formerly been the greater; but it does not follow that they will continue to be so. A good superheater, and a good cylinder-lubricating system for high temperatures, would accomplish this end. These should certainly be within reach of the inventor and the constructor.

The securing of non-conductivity of the internal heat-wasting surfaces of the cylinder would not seem absolutely beyond our reach. A century ago, Smeaton, the greatest engineer of his day, in part accomplished this result by the use of a sheathing of wood on his pistons and cylinder-heads. This cannot be done with the high pressures and temperatures of steam usual to-day; but other plans may prove feasible. Mr. C. E. Emery, many years ago, tried enamelling these surfaces, and with enough success to show that the idea is a good one; though the enamels and coverings then available were not suitable for this purpose. The writer has found a method patented by him some time since similarly effective and possibly practicable, and doubtless other inventors will turn their attention to the problem, ultimately with complete success.*

Could a material be found of sufficient strength and a good non-conductor, of which the steam cylinder could be made, this result would be reached, and the efficiency of fluid of the ideal engine would be practically attained.

Like the best engines of other types, the modern high-speed engine now seems to have been brought, in its best forms, to so perfect a condition that the range for further improvement is probably very narrow, and the gain still to be made must come slowly and painfully. In regulation and in simplicity of construction, in speed of rotation and in general adaptation to its special work, it is comparatively satisfactory. The further improvement must be in economy of its operation and maintenance. Greater efficiency of the working fluid will be gained, as in all other heat-engines, by increasing the temperature of the steam; higher efficiency of the engine as a machine will follow more effective ways of reducing engine friction; but the compounding of the engine must be taken as the last large economical step in its improvement.

The problems now arising in its application are those which come to the engineer in all departments of his work. He must decide what efficiency he can afford to pay for in increased cost of engine; what size of engine he should adopt for a given amount of work; what size of "unit" of power he may best adopt in dividing up the work, if he is to divide it at all, among several engines, and what each subdivision of power should measure. In general, it is now well understood that the engine should be given a lower ratio of expansion than was formerly supposed economical under specified conditions. The ratio should rarely, probably, be greater than three or four in simple non-condensing engines, and at less than 100lb. pressure, or greater than six or seven in simple condensing engines. Compounding enables the engineer to design his engine with a view to expansion down to a terminal pressure—in the latter case of, perhaps, 10lb.—economically.

The unit of power adopted is made the largest at which the engine can be continuously employed in its regular duties, and for some hours together. Every case, and especially in electric lighting, compels the designer to study the problem from many points of view, and to compute probable expenditures and minima of costs for a variety of possible arrangements, before he can finally safely decide just what system to employ or what type of engine is likely to prove best for the intended establishment and plant. Mr. Field's work at the Edison station in Brooklyn, and that of Mr. Henthorn in Providence, are good examples of this problem, carefully worked out, while the plans of the West End Company in Boston, and many of those produced by Mr. Sprague, illustrate the solution of similar problems in street railway work.

* My plan consists in dissolving the iron from the surface of the parts exposed to the action of steam, as the faces of the piston, the interior of the heads and the ports, by the use of acid, thus leaving a thin covering of reduced conductivity; which surface is then, if desired, filled with a still better non-conductor, as the resin of a drying oil, with which it may be saturated. The experiments of Prof. R. C. Carpenter and of Mr. P. M. Chamberlain indicate that this may effect a saving of a large fraction of the now seemingly unavoidable interior wastes.—*Transactions* Am. Society of Civil Engineers, 1890 (Cresson meeting).

SOME DEFECTS IN PHYSICAL TERMINOLOGY.*

BY PROF. A. E. DOLBEAR.

Whewell attributes the failure of the Greeks to make headway in physical science to the fact that their ideas were not appropriate to the phenomena. In a like manner it may be said that we are retarded by the lack of appropriate terminology, and that something will be gained when the terminology is so far reconstructed as to be incapable of misleading one.

As to the nature of energy. In Daniell's "Textbook of the Principles of Physics" the statement is made that "energy is a physical entity," implying that it is an independent, objective something, an existence not conditioned by other physical things, and this idea is so common that it is worth while to closely inspect it. Now, energy is defined as the ability to do work, and work is measured in foot pounds. When we give expression to the relation between energy and work we have, $\frac{M v^2}{2} = W h$, when M is the mass, v the velocity, W its weight and h the height to which W will be raised. But $\frac{M v^2}{2}$ is the measure of energy in the units of work. In absolute units it is proportional to $M v^2$, or, as it is perhaps better to write it, $M v \times v$, which is the velocity of momentum. As there is no such thing known as energy where there are not two factors, namely, a something—a real entity—and a motion, it follows that when there is absolute quiescence there is no energy; and if there be no substance, though velocity be infinite, there is no energy. Hence energy is a *product*, and is not a something that exists apart from moving bodies. It is a product of substance and motion, and is proportional to the amount of motion.

There is, then, no good reason for considering energy as being a mysterious something that has an existence apart from the substance of the physical universe any more than there is for considering the same for motion or for momentum.

It appears that the so-called forms of energy depend upon the form of the motion involved as well as the character of that which is moved. As to the first of these, the kinds of motion that are possible are probably very great in number, but they may all be reduced to their primary forms, namely rectilinear, vibratory and rotary. Combinations of these yield all sorts of others. For instance, two rectilinear will give either a resultant rectilinear, as exhibited in the so-called parallelogram of forces, or a curvilinear, as in the movement of a bullet fired from a gun in other than a vertical direction. A combination of a rectilinear with a vibratory gives an undulatory or wave motion; a rectilinear with a rotary gives a spiral, and so on.

The expression for the energy of a body is not limited by the size of the body. It is as applicable to an atom as to a cannon ball or the earth in its orbit, but it is convenient to change the form of it where the physical conditions warrant it. For rectilinear motions or combinations of them the form $\frac{M v^2}{2}$ is used for both large and small bodies, only such motions of atoms and molecules are called free paths, or the distance between successive impacts.

For vibratory motion, however, the value of v depends upon two conditions, the number of vibrations per second, n, and the amplitude of the vibration, a. These are entirely independent of each other, and either may have almost any assigned value, so that $v = a n$, and the energy is $\frac{M a^2 n^2}{2}$.

For a rotating particle, energy $= \frac{M r^2 \omega^2}{2}$, where r is the distance to the centre of rotation and ω is the number of degrees passed over in one second. It may have substituted for it the expression for rectilinear energy by making v the number of feet passed over in a second.

When the moving body is so large that its motions may be seen, the body is said to have mechanical motion or mechanical energy, sometimes kinetic energy, and when the body is too small to be seen the movements are spoken of as atomic or molecular; and here is where trouble often begins, by failing to keep in mind that the size of a body makes no difference in the character of the motions it may have.

For twenty-five years or more we have been familiar with the expression, "Heat is a mode of motion," and lately we have it in numerous works intended to be exact that "Heat is a form of energy." To illustrate the foggyness upon this matter, I cannot do better than to quote statements from several text-books lately issued. In Daniell's "Principles of Physics," p. 325, there is the definite statement in large print, "Heat is a form of energy." On p. 326 is this statement, "Heat is not motion;" and on p. 444, "The molecular vibration which excites ether waves is a true vibration of the molecule, not a translational oscillation from place to place." Olmstead's "College Philosophy" (Kimball's revision) has it, "There is abundant reason for believing that heat consists of exceedingly rapid vibrations of ordinary matter and of the ether which fills all space." In Avery's "Elements," "Heat is a form of energy. It consists of vibratory motions of the molecules of matter." In "National Philosophy," by Sharpless and Phillips, "Heat like light consists of waves of ether." In Gage's "Elements of Physics," "Heat is molecular motion." In "The New Physics," by Trowbridge, there is the statement that "motion is therefore being continually changed into heat in all the operations of machines." Also, "The phenomena of heat and light are so closely allied that it is impossible to regard them as separate manifestations of energy."

Maxwell says: "Heat is of the same nature as mechanical work, that is, it is one of the forms of energy." Also, "We have no right to speak of this process of radiation as heat;" and again, "Heat can be generated and it can also be destroyed." "For every foot-pound of work so done, a certain quantity of heat is put out of existence."

These quotations are quite sufficient to show that there is no agreement among authors as to what the nature of heat is, nor is there always consistency in the treatment by a given author. There are the contradictory statements that heat is a mode of motion, and that it is not motion—that it is energy, and that it can be destaoyed; that it is ether waves, and that ether waves cannot properly be called heat.

Let it be admitted that a heated body sets up what we call undulations in the ether, that these waves have a wave length determined by the period of vibration of the atoms or molecules, and that the energy of the ether waves varies as the square of their amplitude, and let it be also admitted that there is not the slightest evidence that translational motion of a body of any size sets up waves in the ether, and it follows at once that what we call heat is the true vibration of the molecule and not its translational motion. That is to say, heat is the vibrational motion of atoms and molecules and its energy is proportional to the square of the amplitude of vibration.

If translational motion could impart to the ether any motion, of course a proportional part of energy would be observed by it, and the earth and other bodies moving in it would be slowing up. Now the velocity of the earth in its orbit is something like 17 miles a second, but the velocity of a molecule of hydrogen, the swiftest of all molecules, at 0°C. is but 1,843 metres, or only about $\frac{1}{18}$th that of the earth; so, if the earth movement sets up no waves, the free path of the gaseous molecule can much less. Again, the whole of spectroscopy teaches the same thing, namely, that the ether waves are set up by the internal vibrations of molecules, and not by their external motions. As no other kind of motion is known that can produce similar effects, it would seem to follow that heat will be correctly defined when the character of the motions are specified.

When motion of one kind is transformed into another kind, the character of the energy is transformed also, and what a given amount of energy will do depends altogether upon its form, not upon its quantity; that is to say, vibratory energy has possibilities that do not belong to rotary or rectilinear. There is the assumption that heat exists in three forms: 1, the true vibration of the molecule; 2, the translational free path motion; and 3, the ether undulation when as both the translational motion and the ether waves are the results of the vibration of the molecule, the one by impact, the other by absorption; the one a transformation of vibrating into rectilinear free path motions, the other both a transformer and a transformation. To call each of these by the same name is to confound entirely different phenomena—an effect with a cause.

In every case where there is a so-called transformation of energy, what really happens is a transformation of motion, hence if the various forms of motion have specific names the inconsistencies will all disappear.

It is but a short time ago that we were taught that there were three kinds of radiations from heated molecules—heat, light, and actinic rays; but photography and the bolometer have rendered that statement quite untenable, for it has been discovered that what ether waves will do depends upon what they fall upon. One body will have its temperature raised, and we say it is heated; another body has its molecular structure broken up, and we say it has been chemically acted upon; and still another has a sensation incited, and we say it is the effect of light. Now that light is known to be a purely physiological phenomenon, and that there is no such thing apart from eyes; and even with the probability that what goes on in the eye itself is of the nature of photographic action, the general explanation of all the phenomena has been changed, but the terminology remains to mislead even those who are more or less familiar with the facts, as when one speaks of "the velocity of light," of the existence of "dark and light heat rays," and of the "temperature of space." If light be a physiological phenomenon, it cannot at the same time be an undulation in the ether; neither

* Abstract from an article in the *Electrical Engineer* of New York.

Digitized by Google

can dark and light be applied to the same phenomenon, nor can empty space have a temperature, as temperature is a condition of the molecules of matter. The term "radiant energy" has sometimes been used as a substitute for radiations, and in Daniell's "Physics" the whole range of undulatory motions in the ether is treated under the general head of Ether Waves. This is better than the other; yet between these two there is this discrepancy, that motions of any sort cannot properly be called energy, for, as said before, energy is a product and motion is but one of the factors.

In the subject of electricity the lack of definitions in the terminology has led to a great deal of confused thought, but our actual knowledge of the character of electricity is much greater than many suppose it to be. Maxwell and others have asserted that whatever it may be it is not energy, while others, as represented by Preece, assert that it is energy. Curiously enough, Maxwell declares that it cannot be energy because electric energy is a *product* of electricity, E, into a current, C.

Edlund and some others have thought electricity to be identical with the ether, while still others have imagined it to be a fluid, or two fluids, or some kind of matter with the fundamental property of matter, namely, *mass*, left out. It is not very difficult now to see how such varied conceptions arose. An electrified body affects the space about it, or, as we now say, it produces an electric field which is known to be a stress in the ether, and that implies a strain in the electrified body. It is also known that such stress is propagated in the ether with the common speed of ether waves, namely, 186,300 miles per second. The speed of this movement has been measured by so many and in so many ways that there is no doubt about it, and since the experiments of Hertz there is no room for doubt as to the existence of the ether.

What we now know is that states of stress in the ether are propagated at a definite rate in it, which rate depends not upon the source of the movement but upon the property of the ether to transmit movement; so, whether heat movements or electrical movements are antecedent makes no difference. We find no difference in perceiving the relation between the vibratory molecular motions and the resulting waves in the ether, but here is a precisely analogous case of electrified molecules and the ether propagating a motion, which implies, if anything, that molecular motion is the source of the ether displacements. One person will give chief attention to what is going on in the electrified matter, and another person to what is going on in the ether, and they come to different conclusions as to the nature of electricity, while a third person who notes their discrepant notions concludes that no one knows anything about it. What we call electricity originates in matter, and there is no evidence whatever that it ever originates apart from it. As Rowland has somewhere said: "It begins in matter and ends in matter." The conditions for its origination are differing and interfering molecular motions, whether in a thermopile, a galvanic battery, or a dynamo; the conditions for its transference are a continuous material conductor, for it cannot traverse a vacuum. The effect upon the ether we call an inductive effect; and just as in heat phenomena we have a transference and a transformation, so is there also in electrical, both a transference and a transformation. In heat phenomena, where matter is placed in the thermal field so that the ether undulations fall upon it, the matter is heated. Likewise, when matter is placed in an electric field the matter is electrified. The cases are exactly analogous, and one is therefore justified in making the terminology appropriate to the phenomena; and whenever there has been a transformation in the motion, another name ought to be adopted and not let the old one do double duty. If molecular motions of any kind be called electricity, then it is not proper to call any effects in the ether by that name. If the effects we study in the ether be called electricity, then do we need a name for what takes place in matter, for one is the effect of the other.

If one adopts the doctrine of the conservation of energy, and also that the matter of the earth is practically a constant quantity, it will lead him to conclude that all the varieties of energy are due to the various forms of motion that matter may have. If, also, one perceives that motion of any kind, at any place, implies antecedent motion, he will not feel the necessity for looking for hyperphysical explanations for any physical phenomena. For instance, when one sees the light and feels the heat from an electric arc lamp, knowing the nature of both the light and heat as being but particular forms of motion—one in matter, the other in the ether—he could logically look for nothing but some kind of motion that had been transformed to produce such effects. It is entirely immaterial what the character of the motions may be that produce electrical effects—that may remain to be determined by experiment—just as in the case of heat after the work of Sir Humphrey Davy and Count Rumford, it was then settled what the *nature* of heat was, namely, a molecular motion of some sort and not an entity. It is only within a few years that the character of the motion has been determined. In like manner, we may say that we know what the *nature* of electricity is—that it is also molecular motion of some sort to be experimentally determined

There are numerous reasons for thinking it to be a rotation as distinguished from a vibration. One of the chief of these comes from a study of electro-magnetic effects in the ether. It is generally agreed that this magnetic effect in the ether is of the nature of a whirl, or rotation, and in numerous treatises these whirls are pictured, but I no not remember to have noted that anyone has pointed out that a whirl in the ether implies a rotation of a molecule, for a similar reason that an undulation in the ether implies a vibration of the molecule. To me this appears to be necessary, but whether the motion be that or some more complex kind does not so much matter—it will be discovered in time.

There is one more important matter I want to allude to, and that is the expression first used by Maxwell, namely, "Light as an electro-magnetic phenomenon." Waiving for the time the criticism that light, being a physiological phenomenon, is therefore inappropriate here, there still remains this fact, that the ether waves from heated bodies move in straight lines, and unless deflected by the reflections and refractions of matter will continue indefinitely on in the same straight line, making the field of a heated body as extensive as the universe; while the field of an electrified body depends upon the proximity of masses of matter, and practically is always limited in extent, and the observed lines are always curved. So if the two kinds of waves were really parts of the same movement, what is called a ray of light would seldom or never be found to move in a straight line for any considerable distance. If, on the other hand, the wave that originates in a vibration continues in a straight line only so long as it moves in homogeneous ether, and has its place of vibration changed by passing through a space of ether that has been electrically warped, as we experimentally discover to be the case, it would seen to follow that the two kinds of motion in the ether are fundamentally unlike. Either can exist without the other, and therefore they ought not to be called by the same name.

MODERN CONCEPTIONS OF ELECTRICITY.*

BY DR. LOUIS DUNCAN.

The electrician is mainly concerned with the transformation of energy, and material only affects him as it modifies these transformations. The principal virtue of electrical applications lies in the ease with which they allow transformations otherwise difficult to be made. For example, I have here some pieces of apparatus which will illustrate this,—motor, Geissler tubes, piece of carbon, induction coil and jars. What we want to understand is how this transmission takes place.

For the last half-century the great advances in physical science have been through the application of the law of the conservation of energy. Energy disappears at one place and appears in another form, perhaps in another place. The two quantities are equal, or if they are not equal the difference must be accounted for by some loss which must be discovered. The law leads readily to equations, and these have given results of great importance. But, in the last few years the attempt has been made to trace the path of the energy, which leaving one place appears at another. We try to label a given portion of energy—the energy in a given piece of coal, say—and to follow it into the boiler, and then to the engine, and then, perhaps, to a dynamo, and finally, as electric energy to this electric lamp. It has suffered a number of changes, it has passed through many forms, but, finally, that individual portion of energy has reached the lamp, and being changed into radiations, has started on a journey causing a shudder of the ether through the universe and reaching the confines of space.

It is by tracing these various actions that we have arrived at our present notions, and we have traced them backward, beginning with the energy after it has become radiant.

Ever since the undulatory theory of light began to be held, it became evident that there must be some substance, pervading all space, which would transmit the vibrations which constitute light. It is evident that if light is vibratory, something must vibrate, and as there is no matter in the space between the earth and the other heavenly bodies, there must be something besides matter filling the space. This hypothetical substance was named the ether, and every later discovery has added evidence as to its existence, so that now we may consider the ether as a proven fact. And in late years the notion of the ether has assumed greater and greater importance. Sir William Thomson has advanced the theory that matter itself is but ether under various conditions of motion, and he, together with J. J. Thomson, has in some way proved it. If we can account for matter by modifications of the ether, then ether and energy, with the phenomena incident to them, may give us an entire mechanical explanation of the universe, and we can believe that, as far as this mechanical explanation is concerned, we need but ether and motion. And the importance of the ether to us to-night is this, that it seems more than probable that all electrical

* Abstract of a lecture delivered before the Franklin Institute.

Digitized by Google

actions of whatever kind, and however made apparent, are transmitted through the ether and by it; and, indeed, the term electricity itself may very well be a misnomer, and electricity positive and negative may only be two phases of the ether.

This ether theory is an attractive one. To unify all the phenomena of nature and to refer them to the same cause has been the dream of philosophers for many years. But although the conception is simple enough, the details are to us very complex, partly, perhaps, because we are ourselves entangled in that very complicated modification of ether called matter, and cannot perceive things which in their essence are only too simple for us to grasp.

In order to appreciate the change which has taken place in electrical ideas, let us briefly examine the old notions of what constituted the charge of a condenser, and of how electrical energy was conveyed by a wire. In the first case it was held that when we charged a Leyden jar there was a certain definite amount of the fluid electricity upon it, positive electricity on one coating, negative upon the other. When the jar is discharged the two fluids rush together and neutralise one another with some little noise and heat. The thoughts of the experimenters were concentrated upon the charged bodies. If there were two of them they attracted or repelled one another; this was the important fact. It remained for Faraday to show that the space around a charged body had an important part to play in the phenomenon. Substituting sulphur for air between the coatings of a condenser he proved that the capacity was greatly changed. From that time more and more attention has been paid to the space around charged bodies and less to the bodies themselves, until we have begun to consider the latter as simply serving to make evident to us something which is taking place in the surrounding space. But we will talk further of this in the light of some experiments which I will try later.

Our views about an electric current have also been profoundly changed, but much more lately; indeed, the new ideas have not spread very widely even yet. The old idea was that the fluid electricity flowed through a wire very much as water flows through a pipe. But the new idea is that the energy does not flow through the wire at all. At every point along the wire enough energy passes into it to account for the amount of heating done, but the energy is transmitted by the ether outside the wire. If I am running this motor, then the energy used in running it does not pass through the wire at all, but passes from the dynamo at the electric lighting station to the motor through the ether. The wire acts as the core of a disturbance in the ether, making the transfer of energy possible, but not itself transferring it.

But it is in another field of electric transfer that we have learned most about the real actions which go on, and a great part of our knowledge is due to three men—Faraday, Maxwell, and Hertz. In Faraday's endeavours to unify the different phenomena of nature he was led to look for some connection between magnetism and light, and he found that there was such a connection, the plane polarisation of light being rotated in a magnetic field.

Maxwell, drawing his inspiration from Faraday, investigated the propagation of an electrical wave through space, and found that it followed the same laws as do light waves, and the velocity was the same as that of an electrical constant, which, on determination, proved to be that of light. So he advanced the hypothesis that light is really an electrical phenomenon. The proof of the hypothesis, however, rested on the fact that velocity of the electric disturbance was that of light, and that certain other electric constants bore the relation to optical constants that theory indicated. It remained for Hertz, a young German, scarcely thirty years old, to show by direct experiment that electrical waves are practically identical with those of light, and to put the electro-magnetic theory on a firm foundation. His method was to produce electrical waves of very short period, say $\frac{1}{100000000}$th of a second, and to directly investigate the method of their propagation. I have indicated on a large scale one way of experiment.

In the first place, if we have two tuning-forks of the same pitch and sound one of them, the other will sound sympathetically as it is called. Air waves are formed by the first fork, and these impinge on the second, causing motions, slight at first, but which are successively added, provided the forks are in tune, until the second fork sounds audibly. If the two are not in tune, the successive impulses are not added, but neutralise one another.

Now, is it possible to try a corresponding electrical experiment, and to do the same thing with electrical waves that we have done with air waves? In the first place, when I discharge this Leyden jar, the only thing we see is a flash of light. But if the energy of this charged jar is really stored up in the ether, then the ether is in a state of strain just as a stiff steel spring would be if it were fastened at one end and the other pulled aside. When we let go the spring, it will vibrate for a while, and in the same way when we let go the electrical strain by discharging the jar there will be an electrical vibration, and as the rate of vibration of the spring depends on its stiffness and weight, so the rate of electrical vibration of the jar depends on its capacity and the self-induction of the discharge circuit. That is, if the jar is smaller the time of vibration is less, and it is smaller for a short than for a great length of wire. So, by having a very small capacity and short wire, Hertz has obtained 2×10^8 vibrations in a second; a number comparable with the vibrations of light.

Suppose we have a circuit of wire with a break in it, and suppose I set up vibrations in the circuit; then I have another circuit which also has a break in it, and I can increase the capacity and therefore change the time constant of either circuit by putting these jars in the circuits. Now, if waves are really sent off from the first circuit, and if the two are in tune, then I may get indications in the second. If I put the two circuits out of tune, there will be no indication in the second. You see the results. This experiment shows us that waves of electric energy are transmitted through the space between the circuits, and it is very imperfectly Hertz's method of experiment. With circuits so small that they could be easily carried about, he investigated the direction of the waves and their length. He found that they were reflected like light waves; that they were refractive and, in fact, that they were practicaliy identical. He directly measured the velocity, too, and found it to be, as nearly as he could measure, the same as that of light. In fact, the evidence is all but conclusive that light is an electro-magnetic phenomenon, and we know that light is transmitted by the ether, so we have at least one form of electric energy, which is transmitted by the ether.

Now, let us take up another form of transmission; namely, along a wire. Here we must try to label the energy coming from the dynamo and follow it to this lamp or motor. Poynting and Heaviside first proved mathematically that the energy appearing in the wire in the form of heat rains down on the wire from the space around it, and the matter has an important practical bearing. Suppose I have a tube, open at both ends, immersed in a tank of water, and suppose the length of the tube is great compared with its diameter. I can represent with it the old and the new idea of electric currents. If there is a piston in the tube and if I push the piston through, the water which represents the current will move steadily along the tube; the velocity of each point in its section is the same, it will move as fast near the outside as in the middle. If we move the piston back and forth rapidly, we will have a current alternating in direction; but the distribution of velocity will still be uniform. Now, suppose we remove the piston and simply move the tube in the water. If we move it slowly and in one direction, the friction of the sides will carry the water along with it, the current being represented by the rate at which the water passes a fixed point, and the distribution is uniform. But if we move the tube rapidly back and forth through a short distance, the condition of the water in the tube will be different according as it is near the centre or near the outside of the tube. If the alternations are rapid and the amplitude is small, then the water near the centre may not move at all. In the first case, we have a current caused by a force acting along the wire; in the second, by a force all along the wire on the outside. The effect is the same for both in the case of a steady motion, corresponding to a steady current, and the distribution is uniform across the section, as it is in the case of a steady current through a wire. But in the case of the alternating forces the results are different; a force along the axis giving a uniform distribution, the force acting from along the outside giving a greater motion near the surface. Which of these corresponds with our experience in the case of alternating electric currents? The last does. With an alternating current along a wire, if the period be very small, a very little of the current reaches the centre.

Other experiments show the same thing almost conclusively, namely, that the energy of an electric current is conveyed by the ether around the wire. But if the wire does not convey the current, how does its presence affect the ether in its neighbourhood? With our present knowledge of the properties of the ether it is impossible to say. We may represent the state of things, if we wish, as Lodge has done. He imagines that the ether is made up of a number of cog-wheels meshing into one another, and he further imagines that a conductor consists of wheels which have no teeth, but whose rims can slip over the cogs with a certain amount of friction, and so with a certain production of heat. If we had nothing but the cogs, we could not make them rotate, for they would tend to turn each other in opposite directions and would stick fast. But with a number of wheels over which the cogged teeth could slide, rotation would be possible, and we would have a condition of affairs representing a current.

If the wheels were elastic, then, if we try to turn one of them, there being no conductors around, the wheel would turn slightly, and this partial turning would be transmitted to the next, and so on; there being a definite strain through the whole space due to the stretching of these rubber wheels. And Lodge would represent the charging of a Leyden jar by this—the distention of the wheels representing the strain in the ether. We must then consider the charge of a Leyden jar as represented by a partial rotation transmitted through space with a velocity dependent on the elasticity of

Digitized by Google

the wheels and their mass. When we discharge the jar, the wheels are relieved from their strain and oscillate for a while about their position of rest. If we will consider for a moment, we will see that if there were such wheels half would revolve with, half against the hands of a watch, and this difference in the direction of rotation of the wheels may be taken as in some way representing the difference between positive and negative electricity.

And this model of the ether would in some way explain magnetism. The rotating cogged wheels represent magnetic effects, and if they rotate they must of necessity be included in a current. So we only have to adopt the old theory of Ampère, who supposed magnets were made up of a great number of small currents circulating around the molecules of the magnet, and our model fits in with the facts of magnetism also. But no one—least of all Prof. Lodge—believes that this actually represents the mechanism of the ether. It helps us to have some definite notions, and no one has been more helpful than Prof. Lodge. But whatever the exact nature of the actions, there is not any doubt that some motion of rotation in the ether accompanies electrical and magnetic actions, and that electrostatic actions are caused by a strain in the ether.

We have taken up in an imperfect way three types of electric action, or rather four. Electrical waves, electrical strains or static electricity, and electric currents, and in the latter we have included magnetic actions, especially if we accept Ampère's hypothesis. There is one thing we have not taken up, and that is the passage of an electric current through liquids. But this I will not take up.

So much for the transmission of electric energy; for its sources we can go in many directions. The largest, most important, and cheapest source of electrical energy is the sun. The energy which makes up the organic life on the earth, the energy which causes the growth of every flower and plant and animal comes to us as electrical energy. Through many transformations, after long waiting sometimes, the electrician takes it again; transforms it a second time into electrical energy, and then distributes it for the uses of mankind.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

The following is a complete list of the Provisional Orders which have received Royal assent during the past Session of Parliament. Altogether there were 15 Bills, the last of which (relating to the City lighting) received assent on the 18th inst.:—

C. = Company. L.A. = Local Authority.

Aberdeen	L.A.	Leicester	L.A.
Accrington	L.A.	London, City of London	C.
Ashton-under-Lyne	C.	,, ,,	C.
Ayr	L.A.	Crystal Palace District	C.
Bacup	L.A.	Lambeth	C.
Barnsley	L.A.	London Electric Supply Co...	C.
Bedford	L.A.	Metropolitan Electric Supply Co.... (Includes Paddington.)	C.
Belfast	L.A.	North London	C.

Electric Lighting of Inverary Castle.—On Monday night the electric light was tested for the first time at the Castle, and proved to be very satisfactory.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *August* 15, 1890.

A PROPOSED TELEGRAPH LINE BY THE WHITE SEA.—A telegraph line, which is expected to prove of considerable use to the northernmost part of Europe, is at present under contemplation by the Russian Postal and Telegraph Department, viz., along the borders of the White Sea *viâ* Kala to the Norwegian frontier. It will, according to the present plan, be taken in hand next year, and will no doubt prove a great boon to the Murman Coast, where they now have a post only twice a week.

THE HOLMSTAD INSTALLATION.—This central station is about ready, and will soon begin its work. In addition to the public street lighting there are subscribers for about 500 incandescent lamps.

THE ELEKTRON COMPANY.—The new central station of this Company at Gothenburg has at present a capacity of 4,000 incandescent lamps, but is capable of an extension up to 10,000 lamps. The dynamos are of Crompton and Co.'s make, and the same firm has also supplied the accumulators intended for use during the night and in summer days, and the Company supplies light through the twenty-four hours without necessitating the continual running of machines. The steam engines are on the triple expansion system, with patent safety boilers for 150 lb. pressure, and are so economical with regard to fuel that the consumption of coal only amounts to $\frac{3}{4}$ kilo. per hour for ten 16-candle incandescent lamps. The whole station is built under the directions of the engineering firm of Calvert and Co. The Company does not only supply light, but also power to a number of smaller workshops, such as cabinet makers, venetian-blind makers, &c. Where only power up to ten horse-power is required this arrangement seems to answer very well, as the motor is much cheaper than a gas or a steam engine in first cost, the working is cheap, and the motor is anything but complicated. For the working of a number of sewing-machines in one place it gives great satisfaction.

COPENHAGEN RAILWAY STATION.—In Copenhagen the State Telegraphs have just contracted with Prof. C. P. Jürgensen's well-known establishment about a large installation at the Copenhagen Railway Station, which, however, does not comprise the passenger station. The installation comprises 30 arc lamps and 200 incandescent lamps.

TELEPHONING TO SHIPS AT ANCHOR.—Telegraphic communication has been introduced at the naval manœuvres in Sweden, now going on. On board every ship is a telephonic apparatus and the connecting wires, which are laid out very quickly and taken up along the anchor chains. In the same manner connection can always be obtained with the State Telegraphs, whereby, of course, the whole country can be communicated with. Altogether the telephone is used regularly on board ship in Sweden, where many of the trading steamers are brought into telephonic connection with the town telephone within half an hour of their arrival, an arrangement which has proved itself eminently useful and practical, and the introduction of which is on the *tapis* in various places.

ELECTRIC RAILWAY.—The first electric railway in Sweden is now ready, viz., at Borholm, in Östergötland. It has been built for the local traffic of the Borholm Iron Works, for the transport of raw material and the finished produce, which has hitherto been a very troublesome matter on account of the local conditions. The electric locomotive, which is of American make, works satisfactorily one or more trucks with loads of about five tons each. The electric power is supplied by two Wenham dynamos, which are worked by a 50 horse-power turbine.

CORRESPONDENCE.

ELECTRICAL NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At the regular monthly meeting of the American Institute of Electrical Engineers held on June 17th last, a proposal was submitted to advocate the connection of the names of Franklin and Henry with the names of some electrical units, and in particular to connect that of Henry with the unit of self-induction. I venture to think that this proposal deserves attention. The British Association Committee on Electrical Standards committed itself last year to the adoption of the term *quadrant* as a name for a practical unit of self-induction, and in face of the fact that private enterprise had already coined and set in circulation the name "secohm" for that of a practical unit of the same nature. Both these terms involve a

Digitized by Google

departure from the principle first suggested by Mr. Latimer Clark and Sir Charles Bright in 1861, and adopted by the British Association Committee in 1862, of forming the names of practical units out of the surnames of distinguished investigators.

Objection has been taken to the term "quadrant" in that it conveys the notion of *a length*, and that it is not desirable that the name of a unit should convey the idea of its dimensions on a particular system of measurement, which now is, but tomorrow may be replaced by some other mode. I will not discuss the *pros* and *cons* of this point, but limit myself to the suggestion that the practical unit of self-induction in the system of measurement which employs the ampere, volt, and ohm, &c., as units, should be called a *hen*. Henry first actually observed the effect and invented the term "self-induction," and used it in a memoir published in the *American Journal of Science*, in July, 1832; whilst the account of Faraday's investigations on the extra current was not published until December, 1834. Henry has, therefore, every claim to be considered as the discoverer of the fact and the inventor of the name; and in employing this short monosyllable for the name of that practical unit, we shall do justice to his work, and bestow upon the unit a name which carries no suggestion of dimensions, and which is susceptible of being used in such compounds as *microhen* and *millihen*, convenient for subdivisions of the unit. There is nothing to prevent any one from speaking of true *hens*, or legal *hens*, or British Association *hens* if it is required to be very precise. Instruments for the measurement of self-induction would be appropriately called *henmeters*, and the act of measurement *henometry*. There is more difficulty in recognising the mode in which to embalm the name of Franklin; but I desire to point out that, if a place should be found for him in our Pantheon of units, there is yet another, namely Gilbert, who deserves not to be forgotten. With diffidence I offer some suggestions on a magnetic nomenclature which will give opportunity to use them both. We want two practical units: one of magnetic induction, and the other of magneto-motive force (M. M. F.).

It may be questioned whether our time-honoured phrase, "number of lines of magnetic force" (or of induction) is entirely satisfactory from a practical point of view. The machinery of tubes of induction, surface integrals, &c., is admirable for its purpose, but it is much more suited to the class-room than the workshop.

It is also equally open to question whether the conceptions of magnetic force and magnetic induction derived from ideal visits to imaginary and exquisitely narrow crevasses in magnetised iron, the explorer being furnished with tiny imaginary "free poles" for experimental purposes, are of a nature best suited to assist actual magnetic engineers. Let us suppose all this for the moment set on one side, and adopting ideas well expounded by Mr. Bosanquet in the *Phil. Mag.* for 1883, Vol. XV., p. 205, consider only magnetic induction as something produced in the iron by magneto-motive force, just as current is produced in a circuit by electro-motive force. Magneto-motive force is produced in a magnetic circuit by linking it with current-turns. Let us dismiss the term "magnetic resistance," objected to by some on the grounds that "resistance" involves ideas of dissipation of energy, and speak of the *magnetic pliability* of a magnetic circuit to indicate its capability of experiencing magnetic induction under impressed magneto-motive force.

Then, further, let it be granted that the total magnetic induction in a magnetic circuit is measured in *gilbs*, and that the gilb is the unit of magnetic induction, one gilb being equal to a hundred million C.-G.-S. units of induction, and being defined by the condition that a uniform rate of change of induction in a magnetic circuit of one gilb per second produces an electro-motive force of one volt in an electric circuit linked with it. Let magneto-motive force or difference of magnetic potential along a magnetic circuit be measured in *franks* and let one frank be defined by the condition that a uniform slope of magnetic potential along a magnetic circuit of one frank per centimetre of length produces magnetic induction of one gilb per centimetre of cross-section in that circuit, when that circuit consists of material of unit pliability (permeability).

What is now called "the induction" (B) will be called density of or intensity of induction," and be expressed by gilbs per square centimetre.

The magneto-motive force will be expressed in franks or microfranks, instead of $\frac{4\pi}{10}$ times the ampere-turns (one microfrank = 80 ampere-turns); and the general relation between the magnetic quantities will be that the density of the magnetic induction in a closed magnetic circuit uniformly acted upon by M. M. F. is proportional to the magneto-motive force per unit of length, and to the magnetic pliability of the material of that circuit.

Magnetic pliability is a constant quantity (taken as unity in measurement) for all non-magnetic circuits; but in ferro-magnetic circuits it is a function of the induction or of the magneto-motive force. Tables can be made out from the observations on permeability at various inductions, giving the pliability of different kinds of iron for magneto-motive forces of different magnitudes applied in particular ways.

Suppose, for example, that a ring is wrapped over with insulated wire, and that there are 100 turns of wire on it, and that a current of 8 amperes is sent through it; there are 800 ampere-turns, or 10 microfranks of magneto-motive force impressed on that closed magnetic circuit uniformly. Let the length of that annular solenoid be 100 centimetres. The slope M.M.F. is $\frac{1}{10}$ microfrank per centimetre. Hence, if the ring is of wood or brass, for which magnetic pliability is unity, we have that the density of induction in the circuit is $\frac{1}{10}$ of a microgilb per square centimetre of cross section. If the ring is of soft iron, proper tables would tell us that the magnetic pliability of soft iron under an impressed magneto-motive force of $\frac{1}{10}$th microfrank per linear centimetre is 1,200 units, and hence that for such iron ring the density of induction is 120 microgilbs per square centimetre (12,000 C.-G.-S.).

If the iron ring has a cross-section of two square centimetres, and is wrapped over also with 10 turns of secondary wire, and the primary curent is completely reversed in $\frac{1}{100}$th of a second, the rate of change of total induction through this secondary would be approximately 480,000 microgilbs per second, and create in the secondary a mean electromotive force of nearly half a volt during the time the uniform rate of change of induction was proceeding.

These rough suggestions will perhaps show that from a practical point of view calculations for dynamo and transformer work might be simplified by the use of such units. The employment of a properly simplified nomenclature for the magnetic units will be a gain, and some such modifications as I have attempted to suggest are wanted for workshop use. One cannot readily teach workmen to handle formulæ bespattered with 4π and 10^8, μ and B; but the conception of ampere turns (80 of which constitute a unit) wrapped round an iron magnetic circuit, whether dynamo magnet or transformer core, acting to produce a certain density of something called induction (measured in gilbs), more or less according to the magnetic pliability of the material, grafts on to existing experience with electric currents, electric pressure, and electric resistance, and only wants a proper set of units and names to make it adapted for every day use. Perhaps some of your readers will give you their views on these matters.—I am, &c., J. A. Fleming.

NOTES ON A CURIOUS LIGHTNING FLASH.

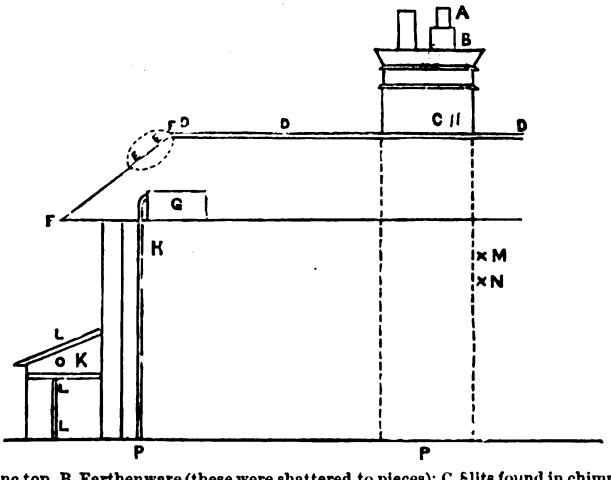
TO THE EDITOR OF THE ELECTRICIAN.

Sir: Knowing that at the present time everybody's attention is turned towards thunderstorms, I send herewith what may be interesting to some of your readers.

On the afternoon of July 17th a storm broke over Surbiton of rather a severer character than has been known for some time past in this neighbourhood. The storm commenced between five and six o'clock, after a very sultry day, accompanied with a great darkness and much rain, the rain falling in dense sheets. At 6:40 I was fortunate enough to see one of those most appalling sights known commonly as globular lightning. The room I was standing in was situated about 30ft. from the ground, when all at once at the time mentioned

Digitized by Google

it seemed to me as if a huge ball of reddish yellow fire was suspended in mid air, about the level of the window. (The colour was that of an electric arc as seen in a dense fog). It did not last a moment, then it rapidly changed colour, and turned to an intense whiteness, more vivid than any other light I have seen, and burst with a terrific explosion, increasing in size many times over, and dozens of small splashes darted out of it on all sides; its brilliancy dazed me for several moments after. I have made several inquiries as to whether anybody else saw it; several people heard the explosion, but only a small boy saw anything of the real thing besides myself.



A, Zinc top, B, Earthenware (these were shattered to pieces); C, Slits found in chimney; D, D, Lead edging; E, E, Portion of roof quite smashed up; F, F, Slate; G, Cold-water cistern; H, Water-pipe, indications of fusing between H and wall; K, Verandah of wood and glass; L, L, L, Iron ridging, gutter and pipe; M, Mantel-piece, broken; N, Iron register, broken and thrown into room; P, P, Supposed earthing.

He states that he saw a big red ball moving along towards the house; but it soon passed out of his sight, owing to his situation in the room; but he heard a terrific bang just after it passed from his view. As far as I am able to discover, it came and went leaving no trace at all of its existence. Another fireball that was also seen in the neighbourhood was said by those who saw it to have been like a red ball surrounded by several smaller ones. I also heard of another one, but up to the present moment I have had no satisfactory details of either of these last two. Below will be found the account of two houses struck simultaneously within a few hundred yards of this house. By the kind courtesy of Mr. Dunlop and Mr. Tiffin, I have been able to make a careful examination of the result of this said flash; and I enclose a rough sketch, which will explain itself. It appeared to have struck the chimney stack, which is common to both houses, and descended inside for a few feet. Here it evidently separated into two branches: one branch continued down the chimney to a fireplace of the first-floor bed-room; here it broke the masonry around the fireplace, also breaking the register and throwing the same into the room in fragments. After this we have no further clue of this branch, except that a large quantity of soot was found on the kitchen range, so I presume that it burst into the kitchen flue, and earthed itself through the pipes under the range, &c.

Now, going back to B, another portion of the current burst through the chimney, leaving two small slits in the same to reach the lead edging, by which it continued its path to E, where the lead stops, and a slate edging commences. A little way down under this slate-edging there is a water tank, and over the tank is a pipe from the hot-water cistern. The lightning leaving the lead, which it fused at the end, made for this water pipe, fracturing a hole some 2ft. 6in. by 1ft. 6in. in the roof, splintering slates and rafters. The slate-edging here is very thick, being about the size of an ordinary man's wrist. A piece of the slate was driven right through the ceiling below, and another was driven with such force as to enter about 1in. into a beam. The hot-water system has been blocked since the house was struck.

We now come to what seems to me to be the most curious of everything; it will be seen by reference to the sketch that a verandah adjoins the house, partially formed of wood and partially of iron; at the spot indicated a round hole of about 2in. diameter has been pierced, as if a stone had been thrown from underneath, as I found glass outside the hole on top; it seemed as if the glass had been fused round the edges, but not to the extent one would expect. A very small quantity of glass was found inside. There was no further indication of the lightning going to earth to be found. I have been looking through some periodicals, and I came across one of Dr. Oliver Lodge's Papers read before the Institute of Electrical Engineers, in which he quotes "Note on the Lightning Flash at Antwerp Railway Station," by M. Melsens. It seems to me, on reading this, that this case bears a little resemblance, although the fusing of the glass in this instance is very slight. The fusing of the glass is on the inside of the glass.

If it was not for the fusing of the glass, which is very slight (which glass is still preserved), I would naturally think that this hole was caused by a piece of slate in falling, &c. I would also here note that the verandah door was wide open. That the house next door, which is only a few yards off, and certainly higher, is thoroughly well protected by lightning conductors. Also that except for the fusing between the different pipes on descending the house, and also of the lead, there is no indication of scorching or charring.—Yours, &c.,

Surbiton, July 22, 1890. D. F. Adamson.

TRADE NOTES AND NOTICES.

TENDERS WANTED.—Tenders are required for lighting the parish of Heavitree with gas, electricity, or otherwise, for three years from October 24. Particulars may be obtained from Mr. Geo. Havill, jun., Fore-street, Heavitree, to whom tenders are to be sent by the 30th inst.

——— The Kinsale Town Commissioners also require tenders for lighting the town for twelve months. Tenders are to be sent by September 1 to Mr. J. F. Hegarty, acting clerk, Town Commissioners' Office, Kinsale.

WOODHOUSE AND RAWSON UNITED (LIMITED).—This firm have been awarded a silver medal for their show at the Exhibition of Fire and Life-Saving Apparatus now being held at Amsterdam.

THE LIGHTING OF SMYRNA.—In his last report to the Foreign Office, Her Majesty's Consul-General states that the electric light is installed in several private establishments at Smyrna, and proposals have been discussed for adopting it in the place of gas, by which the streets are now illuminated. This change, the Consul thinks, is likely to be carried out in the near future; the Gas Company, which is a British corporation, being quite prepared to change their plant as soon as the Municipality offer them a reasonable and durable contract.

DISC-CUTTING TOOL.—The Martignoni disc-cutting tool was shown in operation at the show-rooms of the Machinery and Hardware Co., Queen Victoria-street, yesterday. This tool is another addition to the numerous inventions for saving forging, careful grinding and the waste of material due to short ends, &c. The tool consists of a disc, whose edge is formed to the necessary shape, and part of it is notched away to give a cutting edge. Grinding must be done by a thin or special emery wheel, grinding always to a radius. The system appears to be considerably more expensive than that of Messrs. Smith and Coventry, and will, probably, notwithstanding its merits, meet with a similar opposition. The idea seems to be specially useful in the case of screw chasers. The tool is then merely a slice of a single fluted tap. These tools can be removed from the holder, sharpened, and reset with the certainty of perfect accuracy. If they can be supplied at a reasonable price, and if turners can be induced to use them, they should, in many cases, prove to be very useful.

COMPANIES' MEETINGS.

General Electric Company (Limited).

The statutory general meeting of the shareholders of the General Electric Company (Limited) took place on Tuesday, at the offices, 71, Queen Victoria-street.

Mr. GUSTAV BINSWANGER (the Chairman of the Company), who presided, stated that the business of the Company was divided into three departments—electric lighting, electric bells, and the works at Manchester. The result of the trading was that they were able to recommend a dividend of 15 per cent. on the Preference shares, and of 7½ per cent. on the Ordinary shares, carrying, at the same time, a sum of £637 to reserve. This result must be considered extremely satisfactory, inasmuch as the earning power of the Company upon the actual capital invested was more than 25 per cent. per annum. The business was continuing to show a very substantial increase, and as the winter was the best time for a business of this description, they had every prospect of being able to double the returns. The Chairman concluded by moving the adoption of the report and accounts.

Mr. MYERSTEIN seconded the resolution, which was unanimously agreed to, and the dividends as recommended were also declared.

Mr. T. J. Seel was re-elected auditor of the Company.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

ATLAS ENGINE COMPANY (LIMITED).—Registered with a capital of £12,000 in £1 shares. Objects: To acquire the Atlas Engine Company, at Poole, Dorset, and to carry on the business of engineers, electricians, electric light contractors, dynamo manufacturers, &c.

GORDON ELECTRIC TRACTION SYNDICATE (LIMITED).—This syndicate was registered on the 13th inst., with a capital of £2,400, in £10 shares, to purchase the invention of John Gordon, of a system of electric street car traction, the provisional protection for which is dated 5th May, 1890, No. 6,083.

NONPAREIL ELECTRIC SYNDICATE (LIMITED).—This syndicate was registered on the 13th inst., with a capital of £6,000, in £10 shares, to acquire the letters patent No. 1,757, of 1889, for a new and improved coin freed machine for giving electric shocks, granted to Joseph Mason.

TRUJILLO RAILWAY (PERU), LIMITED.—Registered by Smiles and Co., 15, Bedford-row, W.C., with a capital of £500,000, in £1 shares. Object: To acquire, construct, repair, complete, equip, maintain, and work railways, tramways, telegraph and telephone lines and other means of communication for appliances of a similar nature in Peru, and for such purposes to acquire all or any of the rights of the Peruvian Corporation, under any concessions or contracts relating to any such means of communication or appliances; to carry into effect an agreement, made August 13th, between the Peruvian Corporation of the first part, Thomas Edwin Webb, as trustee on behalf of a company to be incorporated under the name of the Trujillo Railway of the second part, and Michael Paul Grace of the third part.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 15th amounted to £4,838.

HALIFAX AND BERMUDAS CABLES.—In the House of Commons, on Thursday last week, on the vote of £28,375 for subsidies to telegraph companies, Dr. Cameron moved the reduction of the vote in respect of the proposed subsidy to the Halifax and Bermudas Cable Company in connection with the cable recently laid by them. In the course of a long speech Dr. Cameron complained that the House had not been informed of the actual contract under which it was proposed to pay this subsidy. He took exception to the prospectus of the Company, and further complained that although the nominal capital amounted to £50,000 he had found, after inquiry, that only £35 was held by the seven subscribers to the Company. He thought that if the Company came to grief the Debenture holders would have the right to tell the Ministry that a public warning against the prospectus should have been set out. Mr. Jackson, the Financial Secretary to the Treasury, said, in reply, that he had already given a full explanation of the facts of the case, and that he must decline, on the part of the Government, to accept any responsibility for statements made in the prospectus. The Government had taken a new departure with the object of securing the laying of the cable. The proper security was provided, the capital was subscribed, and the cable was in good working order. He thought the Treasury were to be congratulated on the economical manner in which they had carried out the undertaking. The House seemed satisfied with the explanation, and the reduction of the vote was negatived by a majority of 36.

STOCK EXCHANGE.—Application has been made to the Committee to allow the National Telephone Company (Limited), 2,284 addional shares Nos. 436, 701 to 438, 984, to be quoted in the "Official List."

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended August 15th show an increase of £162 as compared with the corresponding period.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 15, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,718.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

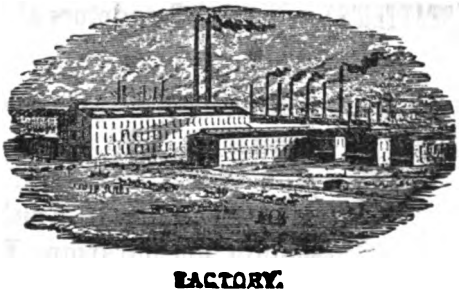
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.



FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 641.—Vol. XXV. FRIDAY, AUGUST 29, 1890. Price Fourpence.

NOTES.

In addition to the Papers the titles of which were given in our last issue, we learn that the following communications will be made to Section A at the forthcoming meeting of the British Association:—"On the Permanence of some Standard Resistance Coils;" "On Two Air Condensers recently constructed for the Electrical Standards Committee;" "On the Specific Resistance of Copper;" "A Comparison of a Platinum Resistance Thermometer and some Kew Standards;" "On Recent Determinations of the Absolute Resistance of Mercury;" "A Report on Recent Progress in our Knowledge of Electrolysis." The work of the Electrical Standards Committee is in very able hands, and is the result of a great deal of research of a high order, probably no feature of the British Association being of so great importance to the electrical engineer. The purely Electrical Engineering Papers are seldom of any great importance compared with those which are read before the Institutions in London, nor do they interest the majority of the frequenters of Section A, while Section G is not, as a rule, remarkable for the novelty of its Papers on either Electrical or Mechanical subjects. Sir William Thomson will contribute to Section A Papers "On Alternate Currents in Parallel Conductors of Homogeneous or Heterogeneous Substance;" "On Anti-Effective Copper in Parallel Conductors or in Coiled Conductors of Alternate Currents;" "On an Illustration of Contact Electricity presented by the Multicellular Electro-static Voltmeter;" and to Section G, "On a New Electric Meter."

A concise statement of the electro-magnetic theory of light has been long wanted. The exposition given in Maxwell's treatise leaves much to be desired, since the essential parts are scattered in various portions of a work dealing with many other subjects. Maxwell's book is very unequal in different parts; for, while aiming at giving a mathematical interpretation of Faraday's views on electricity, a considerable amount of analytical and descriptive matter is introduced which, although of great value, is needless for the main object in hand. Moreover, at the time the book was written there was but little experimental evidence in favour of the electro-magnetic theory, and it was therefore wise to keep it somewhat in the background. Now, however, that the theory has been confirmed by many researches, it is time to state it in a concise manner suitable to an accepted theory.

This task has been undertaken by Prof. Hertz, an abstract of whose work will be found in our present issue. It is highly satisfactory that one who has contributed so much to the experimental verification of the principles involved in Maxwell's theory should be also able to improve upon the mathematical language used by its author. One advantage following from this combination is shown in many of the changes introduced; for, according to Prof. Hertz, and no one is better qualified to judge, some of the artifices used by Maxwell to facilitate mathematical working render the resulting equations less directly applicable to practice than would otherwise be the case.

Prof. Hertz is not the first to show the more perfect form in which Maxwell's theory can be stated; for our readers will remember that in 1885 Mr. Oliver Heaviside, in a long series of articles on "Electro-magnetic Induction and its Propogation," discussed the whole subject with very great ability; and, indeed, the greater number of Hertz expressions are to be found in almost the same form in Mr. Heaviside's work. The priority of the English mathematician is, however, fully acknowledged by the German professor, whose work is none the less welcome and valuable. It forms the most compact exposition of the theory which has yet appeared; while the absence of the quaternion expressions, so frequently used by Mr. Heaviside in analysis, will render it possible for a larger number of readers to follow the reasoning.

The letter of Major Flood-Page in *The Times* on "Fire Offices and Electric Light," of which we gave a brief abstract last week, has given rise to a correspondence in which Mr. Verity, Prof. Silvanus Thompson, and Mr. Campbell Swinton have taken part. Mr. Verity points out that the matter concerns others than the Fire Offices. The supply companies must be satisfied, and the contractor, "who could do his work more speedily and at a lower rate if uniform requirements were insisted on" and it "greatly concerns the house occupier who wants to be left in peace." He says that "it is an open secret that the great difficulties experienced in drawing up the *minimum* tests of efficiency have so long delayed the anxiously-expected Board of Trade regulations." We fear that Mr. Verity and others will be somewhat disappointed to find that these regulations, which we publish in another column, deal very briefly with the details of internal wiring. Rules 18 to 23 are practically the only ones, and Rule 22 dismisses

Digitized by Google

the actual question of "fire risk" in two lines. Mr. VERITY urges that the Institution of Electrical Engineers is "the best and proper body" to grapple with the question; but Mr. CAMPBELL SWINTON points out that the Institution rules were drawn up "by a number of electrical scientists who, though of the highest eminence in their respective spheres, had, and can have had, but little or no experience of the practical difficulties that crop up in actual work," and suggests that they should appoint a Committee of "men who have actual practical experience in wiring houses, and in supplying current from central stations, and not mere theoretical knowledge, however eminent." Prof. SILVANUS THOMPSON joins with Mr. VERITY in acknowledging the indebtedness of the electrical industry to Mr. MUSGRAVE HEAPHY for the high standard of work which he has undoubtedly been the means of bringing about; but thinks that the rules of the Institution "owed their origin to an absurd outside jealousy directed against the Phœnix Fire Office; and asks "Why can we not all agree to accept them?" The answer is, we think, summed up by Mr. VERITY—"They leave too much to the discretion of the Surveyor."

IN connection with the list of Provisional Orders granted by the Board of Trade this year, and which we published in our last issue, it may be interesting to compare the actual results of the memorable electric lighting boom of 1889 with its promise. By the middle of last year no less than 474 notices of intention to apply for Provisional Orders had been served upon the various Local Authorities of the United Kingdom by some 60 electric light companies. This rush of notices, it will be remembered, created considerable alarm amongst the recipients of these "intimations of intention to apply," and a large number of Local Authorities immediately decided to obtain electric lighting powers themselves. However, by the end of 1889 only 161 applications, including those of the Local Authorities, were still being persevered with, and in the result only 74 Orders were granted. The ratio of the result to the intention was, therefore, in this instance about one to six.

LAST year the Board of Trade issued in all 11 Provisional Orders and two Licences, of which one Order and the two Licences related to Local Authorities. This year nearly 60 per cent. of the Orders have been granted to Local Authorities, to whom at least 60 Orders must have been issued since 1882. Up to the present, however, only one Municipal Order, that of Bradford, has been actually worked, although both Brighton and St. Pancras are at last fairly committed to large schemes. The number of Orders issued for metropolitan areas within the last two years is 17, all of which have been granted to companies, and the metropolis may, therefore, be considered as well equipped in this respect.

THE non-delivery of telegrams is always a fruitful subject of complaint whenever it is started in the newspapers, and the columns of *The Times* have been lately overflowing with it. Correspondents who adopt this means of airing their grievances are, if we may judge from their letters, sometimes unreasonable, often illogical, and occasionally contradictory: so much so, indeed, that we are half inclined to suspect that the people who have most to complain about do not trust their pens to describe it. For it may be safely conjectured that these outward signs of dissatisfaction, feeble as they are, are the sure indications of a real grievance that calls for remedy of some sort. Ever since the introduction of sixpenny telegrams, when every word in the addresses as well as the text has been charged for, a growing tendency has manifested itself on the part of the public to be unduly brief, and on the part of the Post Office to be unduly resentful of the consequent curtailment of the addresses. This is a result which indeed the Department itself has partly, if unwittingly, encouraged by sanctioning registered addresses, the public arguing that if a message can be delivered without any address to speak of when a fee is paid for registration, it can be delivered with equal certainty without such fee. Besides this, the habit of brevity in the message is bound to extend itself to the address, with consequent difficulty in delivery.

IT seems to us that it is idle to do battle with this habit by the drastic but fitful punishment of non-delivery. No doubt in a few instances non-delivery is not only excusable but unavoidable, as in the cases of several persons or streets of the same name; but in many others a little extra trouble would ensure the due delivery, and this trouble it would seem the Telegraph Department sometimes, though not always, declines to take; while, on the other hand, the Postal Department justly prides itself upon the wonderful skill with which illegibly written names are deciphered, and letters with absurdly inadequate addresses find their right destination. There is an element of uncertainty about the telegraph delivery, and the public, judging from *The Times* correspondents, are generally inclined to take the risk. Now, the true corrective of this state of things is for the Department to do all that reasonably may be done to deliver a telegram, but to take its time about it, and let the recipient know that the time has been needed. At this moment we have before us a letter which had gone astray through our correspondent addressing us incorrectly. It bears a stamp mark and some writing, which tells us plainly enough that a lot of time has been lost through the improper address; and we shall not fail to inform our careless correspondent of the fact. Why not adopt some such method for insufficiently addressed telegrams? If they were conspicuously stamped, "DELAYED IN DELIVERY THROUGH INSUFFICIENT ADDRESS," we fancy the warning would not often have to be repeated, and the Department would in every case tender its explanation on delivery. This would disarm complaint if reasonable pains were taken to deliver the message; whereas there seems no excuse for some of the cases of intentional non-delivery which have raised the indignation of the writers of these letters to *The Times*.

THE final arrangements have been made with the French Government for the new telephone cable, about which we gave definite particulars in our issue of the 1st inst. (page 342). We understand that Mr. PREECE went to Paris last week, and submitted the specifications and settled the necessary details.

Digitized by Google

Tenders have been invited, and will be received to-day; and the order for the cable will probably be given early next week, other operations being pushed on at once. It may be expected that details of the recent experiments, and an account of the proposed line, will be given at the meeting of the British Association.

Electric Traction in Paris.—An electric tramway is now being laid down between the Trocadéro and the Place Rigalle.

Canterbury.—At a meeting of the Town Council last week it was decided that application be made to the Board of Trade for a Provisional Order.

The Electric Launches at Edinburgh.—It is stated that over 40,000 passengers at penny and twopenny fares have been carried in the electric launches at the Edinburgh Exhibition.

The "Elektrotechnische Rundschau."—On and after the 1st October next the *Elektrotechnische Rundschau* will be published by G. L. Daube, of Frankfort-on-the-Main, and will appear fortnightly.

Award to M. Carre.—The Gifford prize of 6,000 francs has been awarded to M. Ferdinand Carré, by the Société d'Encouragement, for his improvements in the manufacture of arc light carbons.

A New Alloy.—According to the *Bulletin International de l'Electricité*, MM. Bourbouze et Cie are manufacturing an alloy consisting of 100 parts of aluminium and 10 parts of tin, which is said to possess all the advantages of pure aluminium.

Telegraphic Communication with Tory Island.—The Duke and Duchess of Abercorn inaugurated last week the new signal and telegraph station on Tory Island. In future vessels will be reported from this station, instead of from Malin Head.

The Double Carbon Arc Lamp Patent.—In the action brought by the Brush Electric Company, of Cleveland, against the Western Electric Company, for infringement of the Brush double carbon arc lamp patent, a decision has been given sustaining the Brush patent.

The Meeting of the British Association.—In connection with the visit next week of the British Association to Leeds, a useful "Handbook for Leeds and Airedale" has been issued, under the editorship of Prof. L. C. Miall, of the Yorkshire College.

Personal.—We are informed that Mr. A. R. Bennett, who has been General Manager to the National Telephone Company for nearly eight years, has resigned that appointment, and will cease to administer the Company's affairs in Scotland at the end of October.

Lightning Fatalities.—During a storm at Loebschutz (Germany), on August 9th, some reapers sought refuge under some sheaves. The pile of sheaves was struck by lightning; some of the men were killed by the flash, and the others were burnt to death by the fire to which the flash gave rise.

Electric Railways in Karlsruhe.—A company has lately been formed for the purpose of building an electric railway between Beiertheim and Bulach. According to the *Elektrotechnischer Anziger*, it is also intended to build a line connecting Karlsruhe, Mühlburg, Neureuth, and Eggenstein.

Obituary.—We regret to announce the death of Mr. Julius Sax, which took place on Thursday last at his residence, 108, Great Russell-street, Bloomsbury. We are informed that arrangements have been made which will enable the business conducted by the late Mr. Sax to be carried on as usual.

A New Wire for Telegraph Purposes.—The French Postal Telegraph authorities have recently adopted a new type of telegraph wire, called the Martin bimetallic wire. It consists of a steel core, which is coated with copper, and it is proposed to use this wire both for telegraphic and telephonic purposes.

Cable Extensions.—The German Government has negotiated with the Eastern Telegraph Company for the laying of a cable between Dar-es-Salaam, Bagamoyo, and Zanzibar. The ss. "Amber" recently left London with the cable on board, and it is expected that the cable will be laid and working in September.

Telephone Monopoly in the German Empire.—In our Note last week of the result of the action brought by Messrs. Mix and Genest, of Berlin, against the German Government claims for a monopoly of the telephone, we should have stated that the decision given on July 10th was entirely in favour of Messrs. Mix and Genest.

The Life of Glow Lamps.—A correspondent writes from the United States:—"I have fifteen 32 candle-power 120 volt lamps that have burnt 7,591 hours, and are still intact. They are on an outside circuit, each and every lamp having received full pressure of 120 volts right along." A letter describing another phenomenal record will be found in our correspondence columns.

New Alternating-Current Motor.—According to the *Zeitschrift für Elektrotechnik*, the Allgemeine Elektricitäts Gesellschaft, of Berlin, has patented a new alternating-current motor, depending upon the repulsion that exists between two bobbins placed opposite to one another when they are traversed by an alternating current. This motor, like Tesla's, requires three conductors.

An All-Copper Rail Bond.—In electric railways, the resistance of the rail return depends largely on the connection between adjoining rails. The various forms of rail-bonds at present in use are made wholly or in part of iron, and leave much to be desired in the matter of conductivity. To fill this want, rail-bonds entirely of copper are being extensively manufactured in the United States.

The Chicago Electric Fountain.—The new electric fountain presented by Mr. C. T. Yerkes to the Lincoln Park Commissioners of Chicago is now completed. The fountain contains over 200 large jets, all of which are in play together and throw varying streams to the height of 75ft. In addition to these there are numerous smaller jets. The fountain has cost $50,000. Very satisfactory tests have been made.

Electricity and Soapmaking.—According to *La Lumière Electrique*, soap makers are trying the electrolysis of sea-salt solutions, with a view of obtaining caustic soda, from which to prepare the soda so largely used in the manufacture of soap. It is not necessary to push the electrolysis until the salt is entirely decomposed; in fact, at soap works soda lyes are used containing from 30 to 40 per cent. of their weight of salt.

Brussels.—Up to the 1st inst. four tenders had been received by the Brussels Municipality for the electric light scheme which it is proposed to carry out in that city. The first is a combined tender by Siemens and Halske, the Allgemeine Elektricitäts Gesellschaft, of Berlin, and the Compagnie de l'Électricité de Liège; the second is by M. Patin, of Paris; the third by Ganz and Co., of Buda-pest; and the fourth by the Société l'Électrique of Brussels.

Electric Lift at Salzburg.—An electric lift has been provided for raising passengers to the plateau of the Mönschberg, a height of 250ft. A battery of 126 cells by the Oerlikon Company supplies current to a Siemens and Halske motor, which winds the cable. The accumulators are charged during the day time by the dynamos at the Salzburg electric lighting station, a special cable having been laid for the purpose. The lift will hold 12 persons and weighs 25cwt.

Bath.—At the last meeting of the Sanitary Committee of the Town Council the inspector of nuisances reported with reference to the smoke nuisance at the electric light works. The Chairman said the black smoke pouring out of the chimney was something fearful, and other members spoke of the seriousness of the nuisance. It was intimated that Mr. Massingham was seeking a reliable smoke-consuming apparatus. Some 20 members of the Gloucestershire Engineering Society recently visited Bath for the purpose of inspecting the electric light works.

The Utilisation of Water-power in the United States.—The Missouri Power Company are building a gigantic dam across the Missouri River near Helena, Montana, for the purpose of utilising the power of the water. The dam is a timber crib structure, 800ft. long and 47ft. high, and the reservoir obtained by its means will cover an area of 429 square miles. The water will be led along a tunnel to the turbines, which will, it is expected, generate 20,000 h.p., and the power thus developed will be transmitted electrically to the mills, &c., at Helena.

Digitized by Google

New Electrical Companies in the United States.—Since January 1, 1890, says the *Electrical Review* of New York, we have chronicled the formation of 482 new companies, which have been incorporated to do business in the electrical field in this country. This list includes the following branches of the industry: Electric lighting, electric power, electric traction, telephony, telegraphy, and the many sub-divisions of the electrical supply business. The average capitalisation of 100 companies, selected from the list at random, is over $150,000. Multiplying this by 482, we get $72,300,000 of capital authorised for investment in the electrical industry in a little over seven months.

The Telephone in Belgium.—The Belgian Bell Telephone Company has just issued its report for the year 1889. This Company works exchanges in Brussels, Antwerp, Charleroi, Ghent, Verviers and elsewhere. During 1889 the numbers of its subscribers increased by 8·5 per cent., and its net receipts amounted to 400,000fr., on a capital of 3,400,000fr., and after transferring nearly 300,000fr. to the reserve fund, it was able to pay a dividend of 7 per cent. on its paid-up capital. At the end of the year 1892 the Belgian Government will be able to acquire the concern according to the terms of the concession, the purchase price being based upon the average net income of the last three years, *plus* 15 per cent.

St. Thomas Charterhouse Schools.—The results of the late South Kensington examinations show that the pupils of this school have again achieved some praiseworthy successes. Out of 61 who were sent up for examination only three completely failed, while several were successful in the four subjects—Mathematics, Magnetism and Electricity, Sound, Light and Heat, and Solid Geometry, one boy obtaining four first classes. In Mathematics 17 obtained a first class, and very few were ploughed. The results in Magnetism and Electricity were exceptionally brilliant, 25 being placed in the first class and 26 in the second. At the City Guilds Technical College late Matriculation Examination all the pupils from this school were successful.

Severe Thunderstorms.—The South of London was visited by a severe thunderstorm on Sunday afternoon last. At the height of the storm the church of St. George's, Wells-street, Camberwell, was struck by lightning. Large pieces of cement were detached from the coping, and in some cases were carried 60 or 80 yards. Severe storms also took place on Tuesday last at Riston-in-Holderness; a farmer was killed by lightning. He had set off to ride to one of his fields, and was shortly afterwards found lying dead on the road, with his horse standing beside him. He was burnt about the head and face. A house at Burslem was struck, and the tiles were hurled from the roof, the gaspiping was melted, and the house set on fire by the ignited gas.

Bremen.—The electric tramway which came into operation at Bremen some two months ago is the first to be carried out in Europe on the Thomson-Houston overhead system. The line, which is one mile long, commences at the Town Hall in the centre of the town, and terminates just within the entrance to the town park. The generating station is situated near the park, and contains a Kirchen engine of 150 indicated h.p., and a dynamo of 84 electrical h.p., having a pressure at the terminals of 500 volts. The copper conductors are carried on insulators fastened to short pieces of steel cable attached to iron masts 20ft. high. There are now in regular service from five to six cars, each of which has two motors fixed in a special frame under the car body. The tramway is, with the exception of one narrow street, double throughout.

The Resistance of Ferro-Manganese-Copper Alloys.—A recent number of the *American Journal of Science* contains an interesting Paper by Edward L. Nichols, on the "Electrical Resistance of the Alloys of Ferro-Manganese and Copper" (from determinations made by Mr. B. H. Blood). The observations show that ferro-manganese-copper alloys decrease in electrical resistance each time they are subjected to a change of temperature. In one case an alloy containing 80·82 per cent. of copper and 19·12 per cent. of ferro-manganese was hard drawn in the process of obtaining a strip suitable for measurement. Its specific resistance at 20deg., referred to pure copper as unity, was 30·38; this resistance gradually diminished as the strip was repeatedly heated to 100deg. and cooled to 20deg., until after seven such heatings it had fallen to 30·072.

The West Metropolitan Tramways Company and Electric Traction.—At the general meeting of this Company held last week, the Chairman said that negotiations had been in progress in respect to electrical traction for several months; but eventually, he regretted to say, the electrical company withdrew their proposal. It was satisfactory, however, that fresh negotiations were in progress with another electrical company, who had expressed their willingness to undertake the work on advantageous terms as soon as the local authorities should have given their sanction. The relations existing between the vestries and the company were of the most friendly and amicable character, and, under all circumstances, he looked forward to being able, when the matter of electricity was settled, to give the shareholders a good return upon the money they had invested in the Company.

Chester.—At the last monthly meeting of the Town Council the Watch Committee recommended that the electric lighting Provisional Order should be referred to the Committee to report upon. Alderman Frost remarked that he thought it would be well to inquire as to the towns where electric lighting was in existence, and if it paid. If it was a source of loss it would not, he said, be a wise thing for the ratepayers to have to make up an annual loss. Alderman Gilbert pointed out that the step they were taking that day was merely to instruct the Watch Committee to glean information. Mr. Farish said that this matter was tentative from the beginning, and the Watch Committee had no intention, so far as he could gather, of hurrying the Council into any hasty steps. They had a gas company; and he thought they were fairly well supplied with gas. The recommendation was then agreed to.

Lightning on a Transmission of Power Circuit.—At a recent meeting of the Société de Physique, M. Hillairet gave an account of the damage caused by lightning to a transmission of power circuit five kilometres long, situated at Domène (Isère). As thunderstorms were known to be of frequent occurrence in this neighbourhood, the line was provided at either end with comb protectors, and care was taken to well insulate the framework of the dynamos from earth, the insulation resistance being about 100,000 ohms. On May 23rd the line was struck, and 19 out of 130 posts were split, showers of sparks were visible at the brushes of the machines, and the protectors, although uninjured, showed traces of violent discharges. The posts which were struck were altogether in one locality, and M. Hillairet attributes this fact to the presence of a sheet of water a short distance under the soil.

The New York Subway Litigation.—The first decision in the suit of the North American Underground and Electric Company against the Consolidated Telegraph and Electrical Subway Company, to which we referred on p. 348 of our issue of August 1st, has resulted in a defeat for the plaintiff company. The North American Company, it will be remembered, wanted the Consolidated Company to be forced to use the Johnstone system of conduits and pay $2,500,000 damages for the failure to use the system. It also wanted an injunction pending the determination of the suit to restrain the Consolidated Company from laying or maintaining any other system of underground conduits than those of the Johnstone system. Judge Beach, of the New York Supreme Court, before whom the motion for the injunction was argued, gave his decision on August 11th, refusing to grant the injunction.

The Rating of Laboratories.—Amongst the appeals just decided by the Camberwell Assessment Committee is one of more than local interest, viz., whether an observatory or laboratory built in the grounds attached to a gentleman's residence for purposes of observation and scientific research, can be said to add to the annual value of the premises. Sir Henry Bessemer, at considerable cost, erected, not long since, an observatory in his grounds, and in due course the overseers assessed it at £100 gross value. Mr. Blanch contended, on behalf of Sir Henry Bessemer, that while the observatory was doubtless a source of amusement and instruction, if the house and grounds were in the market to-morrow a great difficulty would be experienced in finding a tenant who would use the

Digitized by Google

observatory. The building would probably be got rid of at the earliest opportunity, for an observatory was not altogether a "thing of beauty." In the end the Assessment Committee made a substantial reduction on the assessment.

The Magnetic Field in the Jefferson Laboratory.—This laboratory of the Harvard University has one wing specially constructed throughout of non-magnetic materials, so as to adapt it for delicate magnetic or similar research. To test the efficacy of the precautions which had been entered into in the construction of the building, which is 60ft. square and three floors in height, the variation of the horizontal intensity in the magnetic field over the first floor was carefully determined. The result showed that the intensity was far from constant; in general, the variation from the mean intensity did not exceed ½ per cent., though in one room, between two neighbouring piers about 6ft. apart, it amounted to 4 per cent. The principal causes of this variation were traced to certain vertical iron pipes outside the building used for warming purposes, and also to an iron stove used for experiments on the floor above. The brick piers, or instrument pedestals, were also found to be sufficiently magnetic to produce the variations otherwise unaccountable.

The Preservation of Fermented Liquids by Electricity.—Dr. G. Foth has recently published a very exhaustive series of experiments on the subject. His results led to the following conclusions:—(1) Alternate electrical currents, which, when conducted through a liquid, do not decompose it, are not able to kill yeast cells suspended in the liquid. The electrical current, therefore, as such does not exercise an injurious effect on yeast. (2) This effect is first exercised when the liquid in which the yeast is suspended is decomposed by the electrical current. (3) The ozone produced in the latter case is, if not the only, at all events the principal cause through which the death of the yeast is brought about. (4) The electrical current can, therefore, not be employed to kill the yeast in fermented liquids if their chemical properties are to remain unaltered. Electricity, therefore, cannot be used for the preservation of fermented liquids like beer, unless (5) a higher temperature is brought about by means of alternate electrical currents, in fact unless pasteurisation is effected.

Telephonic Communication with Ships.—An experiment was recently made at Madras, of connecting the Telephone Exchange with the s.s. "Clan McArthur." A wire was laid from the Telephonic Exchange to the T end of the pier. At the T end was an iron stand 3ft. high, to which was attached a drum, round which was wound some G. P. covered wire of seven strands of 16·6 gauge. This cable was connected with wire from the Exchange by a brass trap which came in contact with a brass ring which moved round with the drum. The far end of the cable was attached to No. 1 buoy, and was carried thence along a hawser to the stern of the "Clan McArthur," and connected with a desk instrument. The connection between the "Clan McArthur" and the shore was completed in about two hours, and the communications with the Telephone Exchange were highly successful. If sufficient encouragement is held out by the Port and Harbour Trust authorities and the merchants, it is intended to fix a cable to each of thebuoys of the harbour.

University College, Bristol.—We have received a copy of the Calendar of this College for the Session 1890-91, which begins on October 1st. Great attention has evidently been paid to the engineering department, and the time-tables of the mechanical and electrical engineering courses show that the students are given every opportunity of practically applying their book-learning in the workshop and laboratory. A mere knowledge of testing and laboratory work is, however, not sufficient to enable a student to become an electrical engineer, and arrangements have lately been made whereby students will be enabled to spend one or two terms of six months in works during their College career. Many of the local engineering firms have recently consented to give entrance scholarships to their works, and we are glad to learn that negotiations are still being made to bring closer the connection between the College and leading engineering works, for by this means alone are we likely to extract the maximum of advantage from the system of technical education to which we are now committed.

The Stella Mining Lamp.—This lamp is about to be tried by the Mining Company of Anzin, in France, in one of the most dangerous galleries at the bottom of the mine. The lamp weighs about 3½lbs., and gives a light equivalent to about one candle. The current, which is obtained from an accumulator, is supposed to last about 12 hours perfectly constant, but it is capable of being maintained for about 14 or 16 hours. The accumulator consists of two ebonite cells, each containing five plates 3in. by 1¾in., so arranged as to be protected from exterior shock. Two of these plates are of solid per-oxide of lead (known as lithanode), weighing about ½lb., and have a capacity for useful work of seven ampere-hours. The three other plates are of spongy lead, held in position by a light support of high conductivity. It is stated that the more the lithanode is recharged the better it becomes. Whilst working in the mine the incandescent lamp requires about 5 ampere-hours for twelve hours' lighting. It is claimed that the lamp is absolutely safe, and that when plunged into lighting gas much more explosive than fire-damp did not produce any explosion.

Insects and Arc Lights.—Prof. Lintner, State entomologist, has, says the *Scientific American*, made a microscopic examination of the insect collections of a single electric light, and estimates that the *débris* which he inspected represented 33,000 insects. As many of the smaller forms of insect life probably constituted the larger portion of those attracted to destruction by the light, he believes that the average number of insects destroyed in a night by a single electric light is nearly 100,000. The larger portion of Prof. Lintner's specimen collection from one light consisted of minute gnats, midges, crane flies, and similar small two-winged insects. No mosquitoes were discovered among the victims. There were, however, large numbers of plant bugs, which are injurious to vegetation. A number of the moths, and one of the leaf rollers which have made such havoc in the fruit trees this season, were found, as well as other species of the same family. Prof. Lintner, in speaking of his examination, said: "The electric light will undoubtedly prove an active agent in the reduction of insect pests, and also furnish entomologists with many rare specimens and with many species never before seen."

St. Elmo's Fire.—The occurrence of St. Elmo's fire at sea has been lately studied by Captain Haltermann, of Hamburg, who made examination of a number of ships' log-books for 1884 and 1885, reporting 156 cases, in 800 months of observation. He finds a greater number of cases in north than in south latitudes. And of 63 cases observed in the North Atlantic (the stormiest sea in winter) 49 occurred in the months November to April. Of the total (156) only 27 were unaccompanied by thunder and lightning. Snow and hail showers, with strong wind, seemed specially favourable. As to wind, there were instances with all degrees of intensity. The wind was in most cases (beyond 35° lat.) from equatorial direction, and this, with the commonly observed decrease of pressure, indicates that the cases mostly occurred in the front part of depressions. Between the equator and 10° N. lat. 12 cases were observed, and not one in the corresponding region to the south, where the trade wind generally prevails. In the region of the constantly blowing trade wind St. Elmo's fire is never met with. The western half of seas extending polewards from 30° lat. seems to afford the best conditions.

Gear Wheels for Electrical Traction.—After many experiments there is an inclination in the United States to return to the old-fashioned wooden cogs for speeding down motors. The devices which have been tried with the view of lessening noise have generally been found to wear badly. Well-made hornbeam cogs, gearing with cast iron, have been used in this country for many years, and when well greased will sometimes wear less than the iron. The teeth which are used in the gear which is being tried now in America are driven in with white lead, and wedged at the base in the usual way. They are then put into the gear cutter, and shaped in the ordinary manner. The rim, which is made of cast-iron, slips over the blank, being held in place by six bolts. Between the rim and the hub is laid a sheet of oil paper, which prevents corrosion and tends to stop vibration or "bell tone" from the gear. The blank is keyed firmly to the intermediate shaft, and need never be removed;

Digitized by Google

after the wooden teeth have become entirely worn out, all that is necessary is to remove the six bolts and slide off the rim. An extra rim with the teeth in it can then be put on, the entire change not occupying over ten or fifteen minutes. An ordinary carpenter or wheelwright, it is asserted, can recog the old rim and cut the teeth in a half day's time.

The Willatt Electric Drill.—An electrical drilling machine, designed by Mr. W. H. Willatt, electrical engineer to the firm, has just been brought into operation at Messrs. Earles' Shipbuilding and Engineering Company's Works. It has been designed for use on H.M.Ss. "Endymion" and "St. George" (now being built at Earles'), its special purpose being to drill the holes in the 2½in. steel protective decks to receive the armour bolts. This deck is curved and sloping, and thus renders drilling by hand or machine very difficult. The drilling machine stands on three legs, each of which are powerful compound electro-magnets, and capable of lifting 1,000lb. of iron apiece, and have eccentric wheel castors attached to each leg, so that the machine is quite portable. When the machine is brought over the place required to be drilled, these eccentric castors are turned up, thus allowing the magnets to come into contact with the steel deck; the current is then switched on, and they grip to the deck without any further bolting down. The machine carries an electric motor for driving the drill. A hole 2⅜in. in diameter can be drilled through the 2½in. steel deck in 21 minutes. In the Royal Dockyard, at Devonport, to drill similar holes in a similar ship it takes two men half a-day. The current is obtained from the electric light mains, fitted to light the numerous compartments of the ship during construction.

Science Scholarships.—The Commissioners for the Exhibition of 1851 announced some time ago their intention of appropriating an annual sum of not less than £5,000 to the establishment of scholarships to enable the most promising students in provincial Colleges of Science to complete their studies, either in these colleges or in the larger institutions in the metropolis, it being intended that these scholarships should be a supplement to, and not in competition with, scholarships already existing. It has now been decided to allot 17 scholarships annually. The first list of institutions invited to nominate scholars includes eight English, four Scotch, one Welsh, two Irish, one Canadian, and two Australian institutions. The present allotment is to be considered experimental and temporary, and the selection now made of institutions to which nominations are offered will be subject to modification in the future, having regard not only to the manner in which the nominations are exercised, but also to the claims of other universities and colleges which may from time to time be brought before the notice of the Commissioners. The scholarships are to be of the value of £150 a year, and will be tenable for two years, but in rare instances may be extended to three years by special resolution of the Commissioners. They are to be limited to those branches of science, such as physics, mechanics, and chemistry, the extension of which is specially important for our national industries. The scholarships will be tenable in any university either at home or abroad, or in some other institution to be approved of by the Commissioners, and the holders must undertake to devote themselves wholly to the object of the scholarships, and not to hold any position of emolument during their continuance.

A New Photometer.—A civil engineer, M. Lion, recently described an ingenious photometric balance before the Société d'Encouragement. The action of the instrument is based upon the action of light on iodide of nitrogen. The iodide is prepared by the reaction of ammonia upon iodine. It can be manipulated without the slightest danger when it is kept in its mother liquor, and, when exposed to light, the nitrogen set free is proportional to the intensity of illumination. The liberation of the nitrogen begins immediately the light is applied, and ceases as soon as it is withdrawn. The apparatus consists of two closed metallic vessels, the bottoms of which are of glass. Two mirrors, inclined at an angle of 45°, cause the horizontal rays from the sources of light to strike these glass cups containing the reagent in a vertical direction. The two vessels are connected by a very sensitive differential pressure gauge. Before using the instrument, equality of pressure is obtained in the two arms of the gauge by the manipulation of appropriate pistons. If the two reagents are equally illuminated they will give off equal volumes of nitrogen, and the two columns of the manometer will remain at the same level. On the other hand, if there is an excess of pressure on one side or the other it will be indicated by an alteration in the levels of the manometric columns. The source of light which it is desired to compare with the standard is then moved about until a balance is obtained. As the apparatus is always in some degree dissymmetrical, in the same way as a balance can never be considered to be rigorously true, it is necessary to employ something corresponding to double-weighing. The reagents are, therefore, illuminated in turn by the standard light and no balances are obtained. The instrument is made by MM. Alvergniat, of Paris.

Efficiency of the Transformer.—Prof. Ryan replies in the *Electrical Engineer* of New York to the letter of Mr. Swinburne, of which we gave an abstract last week, as follows:—"Mr. Swinburne's letter is as kind as it is just. In determining the instantaneous currents in the primary of the transformer, Mr. Merritt and I used the following method:—Two lamps were selected to be used in the primary of the transformer and 'calibrated' for this purpose by subjecting them to different continuous differences of potential, and observing the corresponding strengths of current that were set up through them. From these observations, then, as data, a curve was determined from which we could read the resistances of the lamps corresponding to any difference of potential throughout the range through which they might be used. The lamps were then used in the primary of the transformer in the manner described in the Paper. When a curve of the differences of potential that were caused by the primary currents producing falls of potential through the lamps was determined, the effective difference of potential was also observed with the electrometer by connecting it direct to their terminals. This effective difference of potential could also be obtained from the same curve of instantaneous values of differences of potential, the two determinations making an excellent check. Then by reference to the curve of calibration the resistance of the lamps was obtained corresponding to the effective difference of potential, assuming thereby that the resistance of the lamps was the same, whether the lamps were subjected to a certain continuous difference of potential or the same numerical effective difference of potential. The ordinates of the curve of instantaneous differences of potential about the lamps were then divided by this value of the above resistance when the resulting curve was the curve of primary current. The correctness of the method then is dependent upon the assumption that the temperature, and, therefore, the resistances, of the lamp filaments remain constant throughout a complete cycle, and from cycle to cycle. Messrs. Humphrey and Powell considered the abstract of a portion of their work that they prepared to read before the American Institute of Electrical Engineers incomplete without a determination of cards of static hysteresis, and of hysteresis and Foucault currents combined, at the periodicity the transformer was worked. These cards they produced in great haste, and by them made the deductions to which Mr. Swinburne calls attention, and incorporated the same in the Paper. They sent their Papers to the Secretary of the Institute to be reported and to have copies prepared for the meeting, and then discovered an error in the determination of these cards. It was then too late to remedy the matter. For these reasons then the plates XII., XIII., and XIV. (*Electrician*, p. 280, Fig. 2, and p. 281, Fig. 5), containing comparisons and deductions from these cards in their Paper, are erroneous and will be stricken from the authorised report of the Institute. The hysteresis loss that Mr. Merritt and I found in the core of the 10-light transformer at a maximum magnetisation of 3,850 lines per square centimetre, was 3,300 ergs per cycle per cubic centimetre, while Ewing's values given for very soft wrought iron, at this same maximum magnetisation, show a loss of about 1,500 ergs, or, roughly, half what we obtained. It is not clear, therefore, why Mr. Swinburne should say that the loss that we found is small."

MAGNETISM IN IRON AND OTHER METALS.*—XXIX.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 430.*)

§ 108. **Effects of Temperature on Magnetic Quality: Loss of Magnetic Quality at a High Temperature.**—It has been known from the time of Gilbert that when iron or steel is heated to bright redness it loses the power of either retaining magnetism or having magnetism induced in it, but recovers its susceptibility on cooling. The same things happen at a higher temperature with cobalt and at a lower temperature with nickel. In general, the change from the magnetic to the non-magnetic state occurs somewhat suddenly as the temperature is raised. Thus, in one of the experiments of Hopkinson—to be referred to presently in more detail—a piece of wrought iron, subjected to the action of a weak magnetic force, was found to be highly susceptible so long as the temperature did not exceed 775°C. In fact, up to this point the effect of heating was to increase the magnetic susceptibility, and at the temperature 775°C. it was many times greater than when the iron was cold. But with further heating an extremely rapid loss of magnetic quality ensued; when the temperature had risen only 11deg. higher, to 786°C., the iron had become practically non-magnetic. Its permeability was then only 1·1, whereas at 775°C. it had been no less than 11,000. If the test be made with a strong magnetic force instead of a weak one the change from the magnetic to the non-magnetic state is less abrupt†, but it is equally complete, and the same temperature as before makes the iron non-magnetic. Hopkinson calls this the *critical temperature*. The value of the critical temperature varies in different specimens: in samples of ordinary iron and steel it has been found to range from 690°C. to 870°C.‡ In an impure specimen of nickel examined by Hopkinson the critical temperature was 310°C.§

§ 109. **Change of Physical State at the Critical Temperature.**—The change from the magnetic to the non-magnetic state which iron or steel undergoes at the critical temperature is only one of several evidences that the metal then suffers a profound change of constitution. The change shows itself in the alteration of other physical qualities as well as those that have to do with magnetism. Thus Tait‖ has found that the thermo-electric quality of iron alters in a remarkable way at a red heat. The alteration takes place suddenly, and there is no reason to doubt that it is associated with other changes that are brought about by raising the temperature to the critical value. Again, as the experiments of W. Kohlrausch¶ and Hopkinson** have shown, the critical temperature is marked by a sudden change in the coefficient which expresses the effect of temperature upon the electrical resistance of iron. The same thing is true of nickel. Perhaps the most striking evidence that when iron reaches the critical temperature it passes—more or less suddenly—from one condition to another widely different condition, is furnished by Barrett's discovery of "recalescence."†† Let a piece of iron or steel be heated to bright redness and allowed to cool slowly; at a certain stage the process of cooling experiences a sudden check. Heat is generated within the substance of the metal as a consequence of the change which the molecular constitution suffers at this critical point; the cooling is arrested, and the temperature may even rise, though the loss by radiation is going on as before. It is in hard steel that the phenomenon is most marked. So much heat is generated while hard steel passes from one molecular state to another at the critical point, that there is a very visible reglow; the surface of the cooling metal turns for a few moments from a dull to a much brighter red, after which the colour continues to fade. The point at which recalescence takes place is the point at which the cooling metal returns from the non-magnetisable to the magnetisable state. This fact, which was surmised by Barrett, has been proved by the experiments of Hopkinson, who has measured the amount of heat liberated during the change, and has, moreover, given further proof that recalescence has an intimate connection with the recovery of magnetic quality, by showing that it does not occur at all in non-magnetisable manganese steel.*

§ 110. **Effects of Temperature below the Critical Point.**—In studying the effects of temperature we may adopt one or other of two distinct methods. We may note the changes of magnetism which are brought about by varying the temperature, while the magnetic force is kept constant; and as a special case of this we may note the changes of residual magnetism which are brought about by varying the temperature when there is no magnetic force in action. Or we may compare the amounts of magnetism which are acquired at one and another temperature when the specimen is brought to the temperature in question before the magnetic force is applied. In other words, we may determine the form which the curve of I or B and H assumes, when the one or another temperature is maintained constant throughout the process of magnetisation, and may compare the curves got in this way at various temperatures. The two methods do not yield identical results, because of the tendency which the magnetic metals exhibit to oppose magnetic change—the property, namely, which gives rise to those effects which are included under the general name of magnetic hysteresis. On account of this property, which all the magnetic metals share more or less, the magnetic condition that is arrived at if we heat the specimen to any assigned temperature first, and then apply any assigned magnetic force, is in general different from the condition that is reached when the order of these two operations is reversed. The same remark applies with respect to the changes of magnetic quality that are brought about by altering the state of stress, or any other physical condition on which the magnetic state of the specimen depends. In the most complete investigations which have yet been made of the effects of temperature on magnetic quality, the plan has been followed of varying the temperature first, and then studying the effects of applying magnetic force. In other words, what have generally been observed and compared are the susceptibilities of the same specimen at different temperatures.

The experiments of Rowland, Baur, and Hopkinson are of this kind. Rowland,† examining the susceptibility of nickel at two temperatures (5°C. and 230°C.), found that at the higher temperature there was much more susceptibility with respect to weak magnetic forces than at the lower temperature, but less susceptibility with respect to strong forces. In other words, when the magnetisation was sufficiently high the effects of temperature upon susceptibility became reversed. The maximum susceptibility, occurring as it does when the magnetic force is tolerably low, was greater at the higher temperature (some 70 per cent. greater at 230°C. than at 5 deg.). In cobalt, again, he showed that the susceptibility with respect to low forces is increased by heating—a specimen in which the maximum susceptibility (κ) was 11·2 at 5°C. had its maximum susceptibility raised to 18·7 at 230°C. The magnetic forces used by Rowland were not strong enough to reverse the effect of temperature in cobalt, but it is now known that under sufficiently strong force the effect is reversed in that metal, as it is in nickel. Baur ‡ has shown that iron behaves in the same way. If we compare the susceptibility of iron at two temperatures we find that the susceptibility is greater at the higher temperature provided the magnetic force does not exceed a certain value, but less at the higher temperature when the force does exceed that value. It is with respect to weak forces that the influence of temperature is most conspicuous. The most complete experiments on the subject are those of Hopkinson, who has given in the two Papers cited above (one dealing with iron and steel and the other with nickel) series of curves of magnetisation at various tempera-

tures, ranging up to the critical temperature at which magnetic quality disappears. A few of his results may be quoted as the best means of giving some account of the connection between magnetic quality and temperature.

§ 111. **Hopkinson's Experiments on the Magnetisation of Iron at Various Temperatures.**—In these experiments the specimens were rings, and the magnetisation was measured ballistically by reversing the magnetising force. The primary and secondary coils were insulated with asbestos paper; the ring was placed in a cast-iron box, and was heated by a gas furnace, and its temperature was inferred from the resistance of the secondary coil, which was measured before and after each magnetic experiment.

A ring of soft wrought-iron, for which the critical temperature had been found to be about 785°C., was examined in successive experiments, at various temperatures, the curve of **B** and **H** being determined in each case, while the temperature was kept as nearly constant as was practicable. The results show that heating the iron to a high temperature (short of the critical temperature) augments its susceptibility with respect to small magnetic forces very greatly. On the other hand, it reduces greatly the effect of strong magnetic forces. For example, a force **H** of 0·075 C.-G.-S. was found to give the following values **B** at the temperatures noted :—

Temp.	10°C.	376°C.	494°C.	603°C.	670°C.	722°C.	744°C.	763°C.	775°C.	778°C.
B	17	41	45	59	120	144	203	294	494	512

At 788°C., the critical point having been passed, the induction had practically sunk to zero. These figures show well

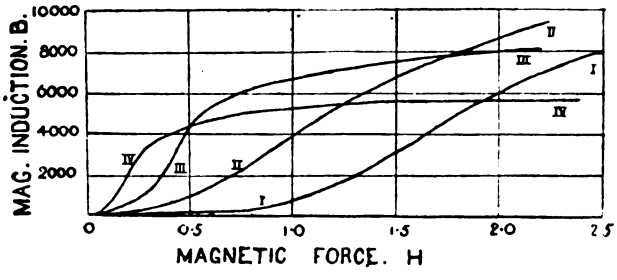

Fig. 77.—Magnetisation of Iron at various temperatures.

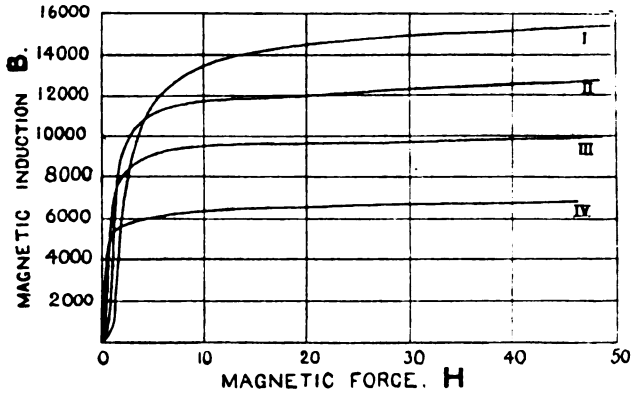

Fig. 78.—Magnetisation of Iron at various temperatures.

the enormous increase of permeability which heating causes at early stages of the magnetising process. On the other hand, a force of 50 units or so gave less than half as much induction at the upper as at the lower end of this range of temperature. Thus the curves of **B** and **H** taken at any two temperatures cross each other, the one for the lower temperature lying at first below and afterwards above the other. Hopkinson has expressed his results in curves of this kind, some of which are copied in Figs. 77 and 78. Curve I. in these figures is for a temperature of 10°C.; curve II. for a temperature of 670°C.; curve III. for a mean temperature of about 742°C. (it varied a few degrees during the observations); and curve IV. for a mean temperature of about 771°C. In Fig. 77 the early portions only are shown; the scale of **H** is wide, in order to display well the crossing of the curves. Fig. 78 shows the

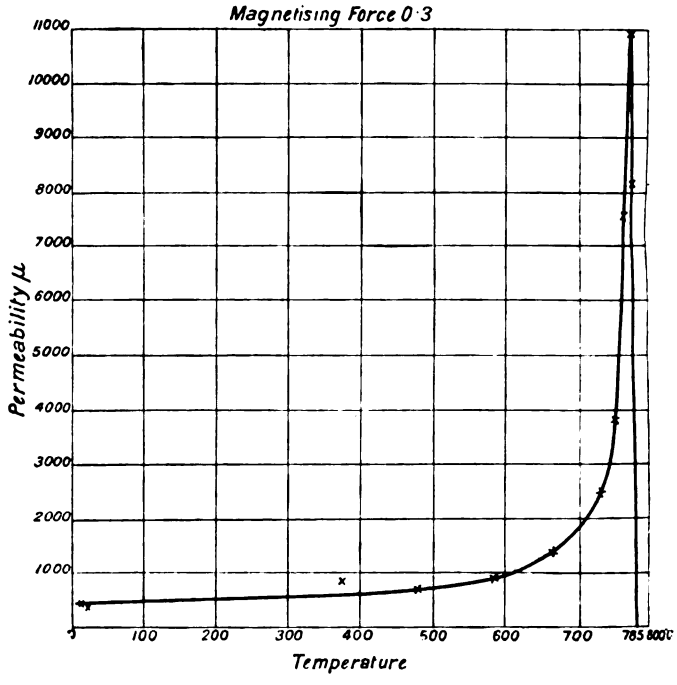

Fig. 79.

whole process of magnetisation with a twenty-fold coarser scale of **H**. The rapid rise and low apparent saturation value in curve IV., where the temperature approaches most closely to the critical value, are to be noted. The same results are shown in a different manner in Figs. 79, 80, and 81, also

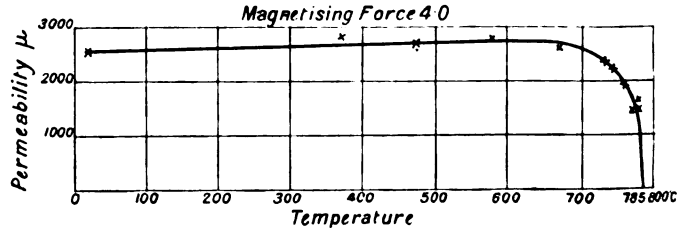

Fig. 80.

copied from Hopkinson's paper. These give the permeability μ in relation to the temperature for three specified values of the magnetising force (0·3, 4·0, and 45). Fig. 79 shows in a striking way the suddenness with which susceptibility to small magnetic force is lost at the critical point, and how this is

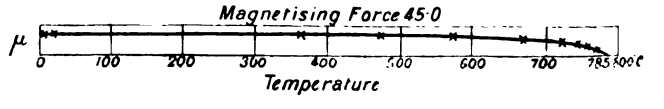

Fig. 81.—Relation of Permeability to Temperature in Iron.

preceded by an enormous augmentation of susceptibility; the other two curves show how much more gradually is the passage from the magnetic to the non-magnetic state when we have to deal with strong forces. In the curve of Fig. 79 the permeability at atmospheric temperatures is 367; as the temperature rises it increases at first slowly and afterwards with great rapidity, reaching the maximum already mentioned of 11,000 at 775°.

ON THE ELECTRO-DYNAMICS OF STATIONARY BODIES.*

BY H. HERTZ.

The collection of principles and formulæ which Maxwell has used for the purpose of exhibiting the theory of electro-magnetic phenomena forms the most complete and most fertile system of all those having the same object in view.

It is much to be desired that a method so essentially correct should be expounded in proper form. The fundamental principles should be stated in a clear and precise manner, the essential deductions should be drawn in the most simple way, and all superfluous notions should be got rid of. Unhappily, Maxwell is far from having attained this perfection in form. He oscillates too often between the reality of facts and the conception of purely hypothetical ideas. Maxwell starts with the notion of forces acting directly at a distance; he seeks the laws according to which the hypothetical polarisation of the ether varies under the action of such forces, and he ends by showing that in reality this polarisation varies without the forces referred to being the cause of the variations. It is clear that such a method does not satisfy the mind, and leaves a prejudice that the result, and the conclusions drawn therefrom, are not correct.

Moreover, this proceeding introduces into the formulæ many principles which are superfluous, and in some respects incomplete, and which are only significant in connection with the old theory of forces acting directly at a distance.

An example of these faulty physical principles consists in the distinction between the dielectric attractions and repulsions and the electric forces acting, as well as the consideration of the ratio of these quantities. These distinctions would have a meaning if we could draw the ether out of the space it occupies, and, at the same time, leave behind the electric forces. According to Maxwell's conceptions, this is perfectly admissible, but it is quite at variance with the ideas gathered from his work.

As an example of incomplete mathematical conceptions I would instance the introduction of the quantity vector-potential into the fundamental equations. In the establishment of our new theory we use potential as a foundation, since by its introduction discontinuous forces acting at a distance are replaced by values determined solely by the state of the medium in the neighbourhood of the point considered. But the substitution of forces by quantities obtained by means of the introduction of vector-potential has only one purpose, that of procuring a mathematical advantage; and it is important that the fundamental equations should state relations between physical quantities rather than relations between quantities used merely for calculation.

This imperfection of form which we have just pointed out renders, in many cases, the application of Maxwell's theory excessively laborious. Thus, when I have had occasion to use it, a long time has been necessary to understand the formulæ, and to distinguish their essential signification. The present Paper embodies the results obtained in my work of revisionand correction.

In 1885 Mr. Oliver Heaviside † worked with the same object in view. The conclusions which he drew from Maxwell's equations are absolutely identical with some of mine, as well as the very simple form which he was induced to give to them. So far, therefore, priority belongs to Mr. Heaviside. In spite of that, I do not consider my work useless. Doubtless the essay is not perfect, but I venture to believe that among all those which have yet appeared mine is that in which most improvement will be found.

I divide the work into two portions. In the first part, A, I expose the fundamental principles and the formulæ following from them. Each formula is discussed, not for the purpose of demonstration, but in order that its meaning and full bearing may be better realised. The groundwork on which I rest is always experience, and the only proof of the formulæ given is experimental. It is clear that each formula cannot be directly demonstrated, but only the entire system of formulæ. The work involves but few equations in addition to those furnished by ordinary rational mechanics.

In the second part, B, I indicate in what way different facts furnished by direct observation can be deduced from the formulæ found, in order to completely establish the correctness of the method.

A.—*Fundamental Principles and their Connection.*

Electric and Magnetic Force.—The interior of all bodies placed in free ether can undergo electric and magnetic perturbations. We do not know the nature of these variations of state, but only the observable phenomena caused by them. We shall suppose these phenomena known, and by their consideration we shall determine the geometrical relations denoting these variations in state. The electric and magnetic perturbations are connected together; for although they may exist at the same time independently of each other, every change of either affects the other. The existence of each perturbation denotes a store of energy, since its change involves a manifestation of energy.

At a given point one can specify the variations of state of each kind with regard to their magnitude, direction, and sense. Consequently, to completely determine either the electric or magnetic state, it is necessary to know either a "directed quantity" or else its three components. We shall, first of all, make an important supposition for our theory, namely, that the knowledge of a single-directed quantity is sufficient to fully determine the variation of the corresponding state. Certain phenomena, such as permanent magnetism, dispersion, &c., are not included in the supposition; for in these cases the electric and magnetic state at any point is determined by more than one variable. Such phenomena are, however, not included in those we propose to consider.

The directed quantity which serves to represent the electric state we shall call the electric force, and define it by means of the mechanical force exerted on an electrified body placed in free space, and submitted to an electric disturbance. For free space the component of the electric force in any direction is represented by the magnitude of the component in the same direction of the mechanical force. For a point within a body, the electric force is defined to be that acting within an empty cylindrical space surrounding the point considered, the cylinder being infinitely thin, and having its axis in the direction of the force.

If we replace everywhere the word "electric" by the word "magnetic," and the electrified body serving for the measurement of electric force by one of the poles of a magnetised needle, we shall obtain the definition of magnetic force.

To fix definitely the sense of direction of the two preceding forces, we shall suppose that the auxiliary electrified body is charged positively, and that the pole of the magnet is the north pole. We shall, for the present, defer the consideration of the units of the two forces.

We shall denote by X, Y, Z the components of the electric force along the axes x, y, z respectively, and by L, M, N the corresponding components of the magnetic force.

Energy of the Field.—The accumulation of electric energy which occurs in a given space is a quadratic function of the three components of the force. This is also true of the magnetic energy. It follows that for an isotropic body, the energy contained in a unit volume is equal to the square of the resultant force multiplied by a constant. This constant may be different for the electric and magnetic energy. We shall measure energy in Gauss' absolute unit, and choose the unit of force so that in free ether the constant becomes $1/8\pi$.

The energy contained in a unit volume of the disturbed ether is then given by the expression

$$\frac{1}{8\pi}(X^2+Y^2+Z^2) + \frac{1}{8\pi}(L^2+M^2+N^2).$$

The dimensions of the electric force are thus the same as those of magnetic force, and are such that their square has the dimensions of energy per unit volume. For isotropic massive bodies the energy per unit volume is

$$\frac{\epsilon}{8\pi}(X^2+Y^2+Z^2) + \frac{\mu}{8\pi}(L^2+M^2+N^2).$$

* An abstract of a paper published in the "Nachrichten von der Königlichen Gesellschaft, der Wissenschaften," for March, 1890; and reprinted in *La Lumière Électrique*, July, 1890.

† See *The Electrician*, 1885, a series of articles on "Electro-magnetic Induction and its Propagation."

Digitized by Google

The new constants ϵ and μ are necessarily abstract positive numbers. We shall call ϵ the dielectric constant and μ the magnetic constant of the body. Evidently their values enable us to compare the electro-magnetic energy of one body with that of another. The nature of the body does not alone determine the value of these quantities. We can, if we choose, make this value unity for ether, but it is necessary to remark that this is only an arbitrary assumption, and not an experimental fact.

Relations between the Forces in Ether or in Non-conductors.—We shall suppose our axes so chosen that when looking along the axis of x in the positive direction, y will be positive when measured to the left, and z positive when measured upwards. Under these circumstances the electric and magnetic forces are connected by the equations

$$\left.\begin{aligned} A\mu\frac{dL}{dt} &= \frac{dZ}{dy} - \frac{dY}{dz} \\ A\mu\frac{dM}{dt} &= \frac{dX}{dz} - \frac{dZ}{dx} \\ A\mu\frac{dN}{dt} &= \frac{dY}{dx} - \frac{dX}{dy} \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (1)$$

$$\left.\begin{aligned} A\epsilon\frac{dX}{dt} &= \frac{dM}{dz} - \frac{dN}{dy} \\ A\epsilon\frac{dY}{dt} &= \frac{dN}{dx} - \frac{dL}{dz} \\ A\epsilon\frac{dZ}{dt} &= \frac{dL}{dy} - \frac{dM}{dx} \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (2)$$

$$\left.\begin{aligned} \frac{dL}{dx} + \frac{dM}{dy} + \frac{dN}{dz} &= 0 \\ \frac{dX}{dx} + \frac{dY}{dy} + \frac{dZ}{dz} &= 0 \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (3)$$

These equations may be obtained either from hypothesis regarding the electric and magnetic constitution of the ether and the nature of the forces acting, or on the basis of known facts. The latter method is much to be preferred, so that the equations can be used to make clear our conceptions of the constitution of the ether.

(To be continued.)

THE HISTORY OF THE COPPER RING.

The fluctuations and changes of the past three years in the Copper Market have illustrated to a degree the old adage that it is the unexpected that happens. Prior to the autumn of 1887 copper for some years had been dropping in price, notwithstanding that the statistical position for a year or two had indicated that consumption was exceeding production, or, at all events, that deliveries were on a larger scale than supplies. It has been asserted in usually well-informed quarters that towards the close of the decadence in price, which culminated in the formation of a syndicate to raise quotations, the market had been artificially manipulated to drive down the price, so that those who had the intention to buy could secure copper at a low level to commence operations from. Be this as it may, in the early autumn of 1887 copper was as low as a few shillings over £38 per ton, and only those mining companies having exceptional advantages of position and richness of deposits could manage to live, and then only at the expense of the shareholders, who in some cases had to go without dividends. Many of the mines shut off work during the period of declining prices; and naturally with a very cheap quotation for the commodity consumption was stimulated just at the same time that production was falling off. According to brokers' statistics, the deliveries for consumption in the 12 months to August 31, 1887, were about 96,000 tons. The supplies amounted to about 81,000 tons, so that there was an excess of consumption over production of about 15,000 tons.

The average monthly deliveries for the 12 months named were 8,000 tons, and the visible stock in hand but little excedeed six months' consumption. There were then the conditions of very small stocks. Retail users of copper had become so accustomed to a falling market, that they too had not cared to work with any appreciable supply, even though assured that they would actually use stores bought To use a colloquial phrase, the market was "bare to the bone;" and yet the use of copper was extending in all the manufacturing industries in general, and in electrical departments of manufacturing industries in particular. Under such conditions the idea of a combination to speculate in copper was not so very wild a scheme, had operators been content with a fair remuneration for the risk they undertook. Under the leadership of a very bold speculator, a combination was formed to raise the price of the metal and control the visible supply. At first this control took the shape of acquiring a considerable amount of the floating supply. Subsequently proposals were made to the leading copper-producing companies in all quarters of the globe to take stated quantities of copper for a period of three years. The scheme was quite French in its elaboration, but a factor was missed.

This factor was the imperishable nature of copper. As soon as prices mounted up to double the quotations, previous to the initiation of the speculation, invisible supplies of copper came pouring into Europe from all quarters. The price made it profitable to melt up all manner of odds and ends; and pedlars even went about in distant countries collecting such out-of-the-way additions to stores of copper as old idols. Thousands of tons of old copper came into the market, and it was estimated that 50,000 to 60,000 tons of second-hand metal was in all accumulated. As the rise went on users of copper sought for means to restrict the quantities they required. The fashion of using brass for household appliances was curtailed. Steel coated with copper was largely used in place of the metal itself, and very quickly there came the feature of production greatly exceeding consumption.

The electrical trades were very seriously embarrassed, as they have no alternative but to use copper, and that of the highest quality. The projected copper telegraph lines of the General Post Office had to be abandoned for the time, although the few which had been erected had proved to be highly satisfactory.

Here are the facts of the second great change in statistics. From October 1, 1887, to the end of September the year following, brokers' lists gave 125,000 tons of supplies (irrespective of invisible stocks thrown on to the market in the shape of remelted copper), while the consumption only reached about 83,000 tons, an excess of supply over consumption of about 40,000 tons, or about 50 per cent. of the total deliveries. Late in 1888 it became apparent that the group who had associated themselves together to control the Copper Market had undertaken a task beyond their strength. Early in 1889 a similar combination in the tin trade broke down, and in March, 1889, the copper combination broke up.

It is in the recollection of everyone what a smash there was in Paris early in March last year. The price of copper, which had ranged about £78 per ton at the close of 1888 and early in 1889, suddenly fell at the close of March to below £40 per ton, momentarily touching £35 per ton, the lowest price in the history of the industry. For some considerable while it did not recover to over £40. Once again statistics changed very remarkably. The brokers' lists indicated that the stocks between the lowest point at which stock stood in 1887 and the highest to which they rose in the early part of 1889, had advanced from a little more than 40,000 tons to about 125,000 tons; and besides the 125,000 stocks which were known of early in 1889 the Paris syndicate held some 50,000 tons "invisible supply," presumably representing the accumulations of old pots, pans, kettles, and idols.

When the break occurred in the market some of the most powerful financial institutions in Europe, particularly in Paris, who had made advances to the syndicate on the security of copper, had involuntarily to take over the speculation for their own account, owing to the failure of the Société des Métaux, which was the head and front of the combination. Under the conditions of the disorganised market any attempt to have sold copper at the time, or immediately after the collapse, would have been impossible. The strong financial houses, therefore, decided to nurse their holdings, and have eventually been suc-

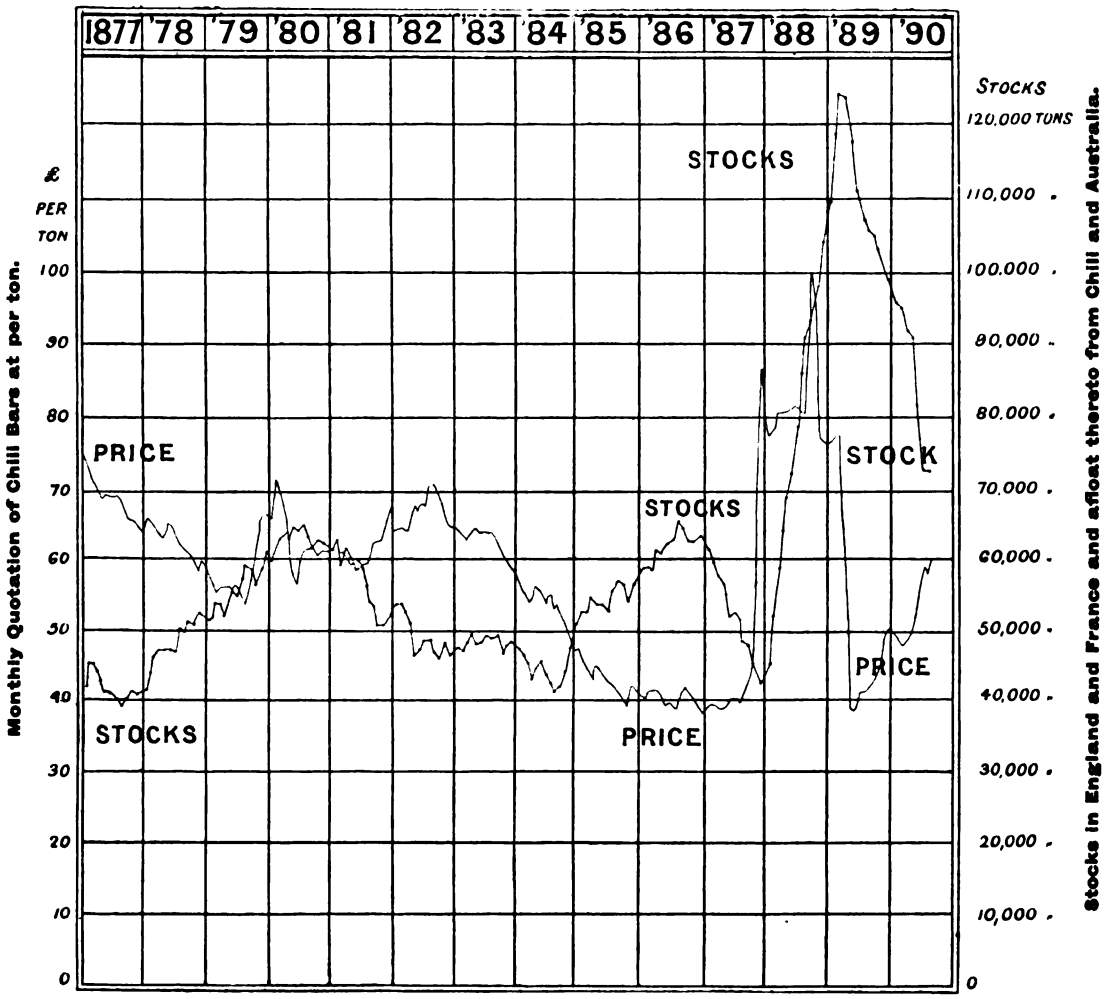
COPPER.

DIAGRAM *showing since 1877, inclusive, the Approximate Course of the Price of Chili Bar Copper (price at the close of each month), and Stocks of Copper received and afloat.*



cessful in disposing of pretty well all without loss, and some indeed at a profit.

Just the very reverse of what happened when copper was rising in price happened when the collapse took place. Consumption was stimulated, production fell off, second-hand supplies had been mopped up, and the market having since been left to the conditions of legitimate trade, supply and demand, the industry has gradually emerged from the chaos brought about by the reckless speculation carried to extravagant lengths by M. Secretan and his friends. Once, again, taking 12 months' supplies and deliveries, we find the fact of a greater consumption than ever before in the history of the trade. The amount delivered to the trade for 12 months to July 31st last was 152,000 tons, and the supplies only reached a little more than 116,000 tons. The bankers and others who were holders of copper have been particularly favoured from the circumstances of activity of trade and a great development of the shipbuilding industry during the last few months. The use of copper, too, has extended very considerably owing to the development of requirements of the metal for electrical purposes. The position is now sounder than it has been for a long period. The average consumption per month of the past 12 months has been not far short of 13,000 tons a month, and the stock of about 72,000 tons consequently represents less than six months' consumption. Owing to the statistical position the price of the metal has been steadily appreciating, until we have this month had it quoted within a trifle of £60 per ton for cash, and over that price for ahead. After the experience of the past we may expect more moderation in market speculation, and the healthy recovery has evidently been due to a belief that with growth of trade and uses for copper the consumption is likely to continue to steadily increase, while few people will be rash enough to seek to control production in such a manner as was attempted in the memorable operation of 1887-9.

We supplement the above remarks with a diagram of statistical information as to the course of stocks in the past and movement in price of copper. Every minute fluctuation in price cannot of course be indicated, so we merely give the quotation at end of each month. The stocks are as given in Messrs. Merton's monthly statistics. Each horizontal space in the diagram represents £10 of price and 10,000 tons of stock. The highest and lowest prices touched in each year supplement the features shown in the diagram, and are added below, as well as figures of the highest and lowest stocks :—

—	Prices.		Stocks.	
	Highest.	Lowest.	Highest.	Lowest.
	£	£	Tons.	Tons.
1877	76	63	46,100	40,500
1878	66¼	55	53,400	44,400
1879	67½	53	58,400	52,200
1880	74½	54½	65,000	59,600
1881	72½	57	62,400	50,200
1882	72	62½	54,000	46,800
1883	67½	56¼	49,900	46,800
1884	57¾	47¼	47,800	40,800
1885	49¼	38¼	57,200	51,400
1886	43¾	39 5/8	66,100	58,500
1887	83½	38¼	61,400	42,300

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Advertisements and other business communications should be addressed to the Publisher. "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN," *and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 5 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consists of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

Orders for the 1890 issue should be forwarded AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

SPECIAL NOTICE.

With the Next Number of "THE ELECTRICIAN" we shall issue a fine STEEL PLATE PORTRAIT of Dr. OLIVER J. LODGE, F.R.S.

BOARD OF TRADE SAFETY REGULATIONS.

The long-expected regulations "for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy," have been issued. They are not on sale at the Government printers, and only fifty copies appear to have been printed. A copy of these regulations will be issued with and will form part of all Provisional Orders in the future. The copy before us is "made by the Board of Trade under the provisions of the Electric Lighting Acts, 1882 and 1888, and of the NOTTING HILL Electric Lighting Order, 1889." The KENSINGTON AND KNIGHTSBRIDGE Company had a draft set of rules which correspond in many particulars to the present regulations, in June last year; and since that time they have been gradually worked into shape. They were submitted by the Board of Trade to the Council of the Institution of Electrical Engineers; but a request from the Electrical Trades Section of the London Chamber of Commerce for permission to see the draft, and to offer comments on it, was refused. Fortunately the former body was not the only source from which suggestions were invited, but copies were sent to the supply companies. The details had been considerably modified when we published the draft as it stood at the beginning of this year (*Electrician*, Vol. XXIV., p. 275). It received further alterations on behalf of the requirements of the Postmaster-General, and it has since been for some months in the hands of certain local authorities. An early form of the rules demanded that transformers should be completely enclosed in metal casing not less than one quarter of an inch in thickness. This clause would probably affect Messrs. SWINBURNE and Co. more severely than anyone else, as the stray induction from the bristling ends of their hedgehogs would give rise to serious losses if surrounded by metal. But not only the transformers had to be so enclosed, but "the whole of the high-pressure service lines, conductors, and apparatus, so far as they shall be on the consumer's premises," were to be so enclosed. This extraordinary suggestion has been abandoned, and the much more sensible demand for enclosing them completely "in solid walls or in strong metal casing efficiently connected to earth, and securely fastened throughout," has been substituted.

Digitized by Google

There is one respect in which the supply of electric energy differs widely from that of gas and water; and one in which those who framed the regulations must have found themselves without any precedent. A leak on a gas service is not a matter of concern to the gas company if it is on the consumer's side of the meter. The consumer will be, as a rule, amply warned by the smell, and explosions are generally due to some additional carelessness. Indeed, in gas or water supply, a leak on the consumer's premises is a distinct source of revenue to the company, if a meter records it; but an earth on an electric supply circuit is not only a matter of considerable inconvenience to the electric supply company, but may have undesirable effects on the other consumers, and on neighbouring telegraph and telephone systems. On this account, rule 23 authorizes the intrusion of an officer on the premises in which the supply company are "reasonably satisfied" that a leak exists to earth, which may be a source of danger.

The property of the consumer in his wires, and that of the supply company in their service lines, meet at a point which is distinctly specified in the definitions as the "consumer's terminals." But the rights of the supply company do not stop here. An inspector may "require the consumer to permit him to inspect and test the wires and fittings belonging to the consumer." This language is suggestive of the unwelcome courtesies of the highwayman, who, with all the politeness and graces of his time, was wont to ask for permission to inspect the purses of travellers when he was reasonably satisfied that they would be a source of wealth. The inspector, moreover, may at all reasonable times, after giving one hour's notice of his intention to do so, enter the "suspected premises" for the purpose of "discovering whether such connection with the earth exists at any part of a circuit." The definitions do not attempt to define what shall be a reasonable time; the notice may evidently be served an hour before the time has become reasonable. The object of this visit of discovery is a leak to earth not exceeding 5,000 ohms. Now, without interfering with the consumer's wires, and certainly without any pottering with his fittings, the officer might easily make his test by disconnecting the supply company's service lines from the neutral landmark of the consumer's terminals, and might test from these to earth, the consumer's wires remaining attached to his terminals. The gas companies' boundary is the main valve or cock; and the limit of the water companies' property is similarly defined. Without going into the question as to who should pay for a switch, it appears that either a double-pole switch, or, preferably, two switches, or a pair of terminals from which the company's service lines can be readily removed, should be the definite limit both of property and of rights. Should it be discovered that a leak to earth exists on the consumer's wires, the company's service lines would not, of course, be re-connected. Since the supply company would not wish to let matters stand thus, the inspector might offer to make further tests or examination of fittings; but permission should be asked for and should be granted before this ought to be done.

We all grumble at the waterworks; they are associated with rates and taxes, while the gas companies provide us with a machine which is the proverbial standard for deliberate falsehood. The electric supply companies should avoid making themselves unpopular; and this compulsory inspection, if it extends to wires and fittings, might be even more objectionable than the occasional disconnection from the mains for the purpose of localising an earth by trying one house or street after another. On June 3rd last year a draft set of rules for use at Bradford was submitted to the Electrical Trades Section, and a few days later these were to be obtained from the Town Clerk, and objections were invited. These rules prohibited the use of any portion of the metal work of electrical fittings as part of the circuit, and demanded an insulation resistance, equal to ten megohms, divided by the total current in amperes. Should any "connections direct with earth, or connections tending to cause earth," be found at any time to exist in an installation, these rules allowed the Corporation to discontinue the supply, even without notice. There is no suggestion of any compulsory "permission" to test the wires and fittings of the consumer. The ninth rule of the Bradford Corporation demands two main switches; and the tenth states that "the proper officers of the Corporation shall have the right of access at all times to these switches." It is a pity that it has been proposed to go beyond this. If the house were shut up, it should not be a difficult matter to disconnect at the junction box; or, where this would occupy too much time, it would be easy enough in most London houses to place the switches within reach of a long key which could be used from outside. The most important matter for public convenience is to disconnect the house, if there is but little doubt that it has a leak; the next thing, for the convenience of the consumer, is to prove the existence of the leak by a test at his terminals, but, to go further and officiously meddle with wires and fittings without his voluntary consent is objectionable. The new rules are much more reasonable than those of Bradford in defining a leak as a connection having a resistance not exceeding 5,000 ohms; but there is a danger that, as in the minimum thickness of walls specified by the Metropolitan Building Act, it may be assumed by those who do cheap work that 6,000 or 8,000 ohms is a decent insulation.

The rules as they now stand will be received with less dissatisfaction than the overhead wire rules, but, as in the former case, some difficulties may arise hereafter when they are put in practice. The overhead wire rules have been incorporated in the new regulations with certain modifications, parts of some of them being transferred to the "definitions." The first regulation of the former set appears as No. 26 of the new issue; the height at which a conductor must cross a street being altered from thirty to thirty-five feet, and the minimum distance from a building being seven feet instead of six. The distance of six feet has been very troublesome to arrange in several cases already, and the change seems to indicate that the Board of Trade do not scruple to throw obstacles in the way of overhead wires. It is to be regretted that the rules relating to aerial conductors have been thus confirmed, since a struggle against the insulation specified in Rule 33 will certainly be carried on; and it is to be hoped that the Board of Trade will confess that they made a mistake in stipulating for an article which they had never seen, and which when made was ridiculous. Rule 27 is a new one. Rule 32 is the same as before, and contains no suggestion as to the method by which it is to be carried out. It was once threatened, unofficially, that a length of rabbit netting would have to be placed under each wire to catch it in case of breakage.

On the whole, the new rules appear to be satisfactory. They do not in any way supersede those of the fire insurance offices, nor will they be likely to render unnecessary those regulations by which the supply companies now protect themselves. They appear to leave but little to the discretion of the inspector; and though they do not exhibit the broad spirit which is noticeable in the other regulations of the Board of Trade, such as those for railways, it may be expected that when things settle down and more experience has been gained, those demands which are found to be unreasonable will be modified, and the rules will not then press hard upon those who do first-class honest work.

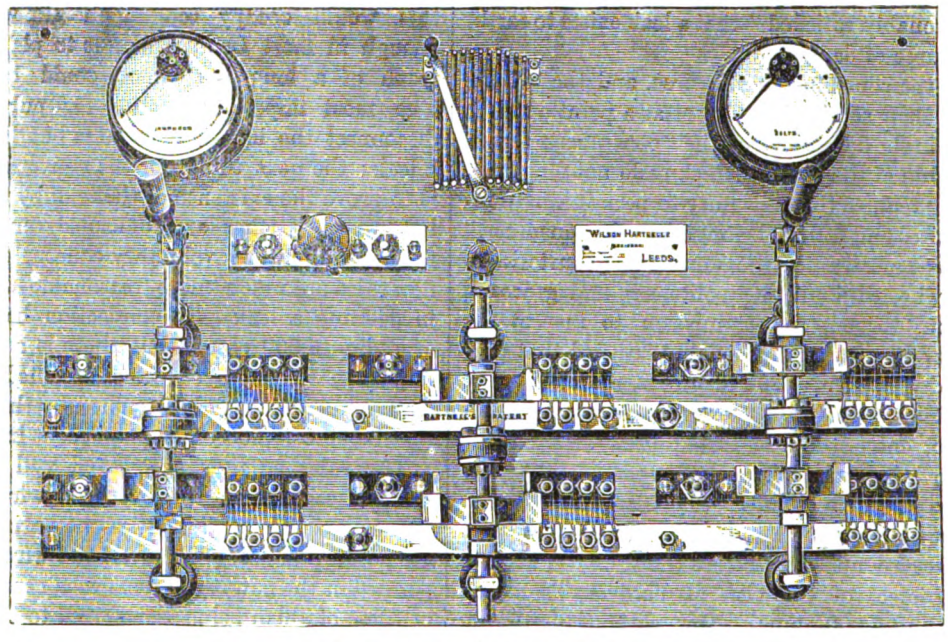
THE EDINBURGH EXHIBITION.—IV.

Mr. Wilson Hartnell's Exhibit.

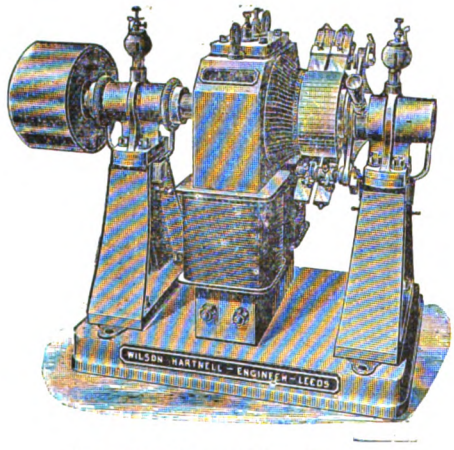
Mr. Wilson Hartnell, of Volt Works, Leeds, occupies a space of some 20ft. by 10ft, in the Machinery Hall. He shows one of his wrought-iron dynamos running at 960 revolutions, and capable of supplying 280 16-candle 64 watt lamps. This is driven by a 6 horse-power horizontal engine by Marshall, Sons, and Co., fitted with Hartnell's automatic expansion gear. Alongside the dynamo is placed a 15 horse-power motor, which is driven from the above machine at a speed of 1,000 revolutions per minute. These dynamos are strong and well made, with large bearings, armature, commutator, and spindle, and they run without any signs of sparking. The one shown has run from the commencement of the Exhibition, with a load equal to about 200 lamps almost continuously; and measurements recently taken show that there has been no wear at the commutator or brushes. The latter have never been touched in any way since starting.

The current is taken from the dynamo to one of Hartnells' patent distributing switchboards, containing three double-pole quadruple break switches, made for carrying 200 lights on each circuit. This is also furnished with ammeter and voltmeter and short circuit plug, as also with a neat variable regulator, which latter is extremely useful for dynamos running all night long. Double pole safety fuses are also employed, and the whole is mounted on a substantial enamelled slate base. The workmanship is of the highest finish. A second switchboard is also shown of three circuits for a smaller installation, and, in addition, there is a motor switchboard in use for the motor already alluded to. Specimens are also shown of Hartnell's patent double-pole switches, such as are suitable for private house lighting, in which all the connections are made on the front of the slate for safety and convenience. No metal work projects on the back side of the slate, it being recessed, and for the most part covered up entirely.

The stand is artistically lighted by incandescent lamps of 16 candle-power to 100 candle-power. Mr. Hartnell supplies current to 100 lamps on Stand 79, and to a few others. He has also one of his small dynamos running, bolted to the end, and driven by a 4 horse-power Stockport gas engine. This was originally designed and supplied as a 30 lighter for Algiers, but as a matter of fact it is driving a load equal to 45 lamps of 16 candle-power each. It runs exceptionally well, and has given no trouble. Two of this type were supplied some 18 months ago for private house-lighting near Belfast, and have not yet required any repairs or renewals whatever.



Hartnell's Patent Distributing Switchboard.



Hartnell's Wrought-iron Dynamo.

THE SANITARY ASPECTS OF ELECTRIC LIGHTING.*

BY W. H. PREECE, F.R.S.

The chief tendency of modern legislation in our British Parliament is to improve the environments of the human frame, so that we may live, and move, and have our being with greater health to the individual, and greater prosperity to the nation. The cleanliness of dwellings, the drainage of towns, the removal of filth, the suppression of nuisance, have not only been specified but the inspection of the means to effect these objects and of their results are defined and insisted upon by Acts of Parliament. People often speak disrespectfully of our grandmotherly Government; but at least in this region of domestic legislation, the control it has exercised over the food we eat, the water we drink, the air we breathe, is of a true parental order, and deserves our unreserved admiration and respect. The Home Office and the Local Government Board act the part of a wise and economic head of the house to the nation, while each commuuity has its own Local Board of Authority to carry out hygienic provisions, to enforce sanitary principles, to prevent infection, to stamp out disease, to sweeten labour, and to prolong life.

I contemplated at one time submitting an historical summary of these features of sanitary legislat ion during the present generation; but not only would the task be very onerous, but it would be

* A lecture delivered on August 26th to the Congress at Brighton of the Sanitary Institute.

Digitized by Google

so lengthy that I should have very little time left to discuss the question set before me—the sanitary aspects of electric lighting.

The propositions that I propose to submit and to demonstrate to you are these :—

1. That electricity and light being analogous forms of energy, the former is naturally the proper source of artificial illumination.

2. That all other sources of artificial illumination being dependent on the absorption of oxygen, and resulting in the vitiation of air-are injurious to health.

3. That the same authority which regulates the sanitation of our dwellings and the supply of our food, should also control the purity of the air we breathe, and of the light we work by.

Light, however it be produced artificially, is simply the equivalent of work that has been done elsewhere. Whether it be by the combustion of tallow or oil, by the burning of coal or of gas, by the glowing of a fine wire, or the formation of the brilliant arc, energy has been expended somewhere, to be transferred and reproduced in some other place in the form of light. The great principle of the conservation of energy teaches us that the amount of energy in the universe is a fixed quantity, that it can be neither created nor destroyed, that it can only be transferred, and that any expenditure of energy—work done—anywhere is the equivalent of energy utilised somewhere else. The rate at which this energy is expended is called *power*, and the amount of power which we foolishly call a *horse-power*, and which we roughly imagine to be equivalent to the power exerted by a horse in drawing a load along a road, is competent to produce an amount of light which is very simply measured. Our standard of light is the light given by a No. 6 sperm candle, burning 120 grains per hour. Now the energy of one horse-power constantly expended will give by the aid of

Tallow	the light of	6	candles.
Sperm.....	,,	8·7	,,
Oil	,,	9	,,
Gas	,,	13	,,
Electric current—Glow ...	,,	248	,,
,, Arc	,,	1,492	,,

The results to the air of these different modes of producing artificial illumination are well shown by the following table :—

Products of Combustion in developing 100 candles per hour.

Illuminant.	Quantity consumed.	Carbonic acid produced.	Water vapour.	Heat.
	lbs.	Cub. ft.	lbs.	Calories.
Tallow	2·2	51·2	2·3	9,700
Sperm	1·7	41·3	2·0	7,960
Oil	1·3	33·6	1·8	7,200
Gas	56 cub. ft.	40·3	2·5	12,150
Electricity.....	(Coal) 2·2 lbs.	0	0	257

Thus we see how very much more efficient electricity is than any other agent for the production of light.

The tendency of the teaching of the present day is to show that the transmission of light waves and of electrical undulations is of the same character and at the same speed. Clerk Maxwell by theory, and Hertz by experiment, have placed this beyond doubt. A current of electricity passing through a fine filament, first raises its temperature, and then as the current is increased in strength, it glows brighter and brighter until finally it is disintegrated and dissipated with great brilliance, and the light disappears. There has been no chemical consumption of material. The passage of the current has resulted in light, and light seems to have been the natural sequence of the flow of electricity. Energy has, however, been developed somewhere. There is a boiler for the production of steam, an engine for the application of power, a dynamo for the formation of electric current.

Gas has to be extracted from coal, purified in gasworks, distributed through pipes, and chemically combined with the oxygen of the air in jets or burners. The simple candle, however, is its own gasworks. We simply apply a match and the flame itself becomes boiler, engine, and light emitter combined. In all cases, therefore, we have to consider—(*a*) the source of energy ; (*b*) the distribution of energy ; (*c*) the utilisation of energy as light.

The sources of energy at our disposal are—Wind, water, coal (steam), gas, and mineral oil. The inconstancy of the wind in our climate renders it inapplicable for the steady and constant supply of power required for artificial illumination.

Water, on the other hand, is an unfailing source of power in some countries, but the quantity required to produce even small effects is opposed to its use anywhere but in mountainous or hilly districts where it is abundant. It requires a quarter of a ton of water falling one foot *per second* to produce one horse-power, or falling ten feet to produce ten horse-power. If we wish to maintain ten ordinary electric glow lamps alight for five hours with a fall of ten feet, we should require 100 tons of water per hour, or 500 tons altogether. At Keswick, in Cumberland, a central station has been established, which is worked by a fall of twenty feet of the water of the river Greta, generating fifty horse-power by means of a turbine. At Portrush, in Ireland, a fall of twenty-six feet generates currents that work a tramway to the Giant's Causeway. Many private houses in Scotland are so lighted. There are innumerable places in the United Kingdom where this power is being allowed to run to waste. The non-utilisation is due probably to ignorance, and ignorance as much as indifference is the great obstruction which all new industries have to overcome, even when practicability and economy are almost self-evident. The power of running streams and of the tides is used in some countries for grinding corn, but the power utilisable is small, and no practical means have yet been introduced to employ them for small installations of electric lighting, though busy minds are actively engaged on this neglected field.

Steam, and therefore coal, becomes in all comparatively flat countries the principal source of power, while, for small installations, gas and mineral oil are extremely convenient, cleanly, and economical suppliers of energy. Indeed, gas as a source of heat is coming more and more into use, and if a cheaper form of gas such as water-gas were distributed for fuel purposes—as it probably will in the future—it would solve the difficulty of the transit of coal, and prevent the possibility of that nuisance, the formation of smoke in the midst of shops and dwellings.

The power that is thus expended is employed in developing electrical energy. Motion is imparted to coils of copper wire in a field of magnetism, and a certain resistance has to be overcome when the lines of force in this field are cut by the wire ; the energy of motion is absorbed, it takes the form of electricity, and, as an electric current, it can be transmitted to a distance, and there utilised. The amount of energy which is found in the form of currents is that delivered by the belt of the engine to the dynamo, less a small amount wasted in friction and in heat in the metal of the dynamo ; but this is so small that it is a common thing now to obtain dynamos with an efficiency of 94 per cent., that is, 6 per cent. only of the power applied to it is lost as heat in the dynamo itself.

If a child has a skipping rope made of copper wire, and, with its face turned due north or south, it skipped, the rope would cut the lines of magnetic force of the earth in the proper direction, the rope would experience resistance, energy would be absorbed by the rope, and electric currents would be developed from hand to hand of the child. The child thus becomes an animated dynamo. The lines of force of the earth flowing north and south are cut twice in each revolution of the skipping rope, but alternately in opposite directions. Hence the currents generated are alternately flowing in opposite directions, and the child becomes an alternate-current dynamo. It is a very simple thing to straighten these currents and to make them flow continuously in the same direction, and to convert these alternate effects into continuous currents flowing in the same direction.

Now, all electric currents require an electromotive force, or a difference of electric pressure to drive them through the resistance of metallic conductors, in the same way that water and gas require pressure to drive them through pipes. This electromotive force in the case of the skipping rope is very minute, because the intensity of the earth's magnetic field is very small (it is only $\frac{1}{20000}$th of the field of an ordinary dynamo), the motion of the rope is comparatively slow, and there is only one cutting conductor. If we increase the number of conductors, their speed and the strength of the field, we can magnify the electric pressure to any amount.

All new ideas require new names to indicate them, and if they are new quantities capable of measurement, they require new units to compare them with numerically. Difference of electric pressure is called voltage, and the unit of comparison is a *volt*. The skipping rope developes only a very small fraction, about $\frac{1}{1000}$th of a volt. There are now dynamos at Deptford which will generate 10,000 volts, and a flash of lightning is the result of perhaps millions of volts. The human frame is very sensitive to voltage, 50 volts is scarcely perceptible, 100 volts give a distinct though slight shock, 500 volts are painful, and 1,000 volts might probably, under certain circumstances, kill a man, 10,000 volts, if effective through the whole frame would certainly destroy life. We have recently read of a deplorable attempt in the United States to utilise this power for the execution of criminals, an attempt surrounded with sickening horrors, the result of the ignorance that exists at present as to the effects of electricity on the human frame.

The unit of electric current by which measurements are made is called an *ampere*. If an ampere be circulated around a bar or ring of iron, it will magnetise it with a definite amount of magnetism dependent upon its dimensions and quality. If it be transmitted through a bath of nitrate of silver, it will deposit four grammes of silver per hour. If it be driven through a fine filament of car-

Digitized by Google

bonised cotton 6 in. long, such as Edison and Swan use for their glow lamps, by an electromotive force of 100 volts, it will develop a brilliant light of 32-candle power.

The actual energy conveyed by the current is measured by the product of the volts and amperes, and this measures the rate at which energy is being transmitted or expended. The unit of measurement is called *the watt*, which is a much more scientific and accurate unit of power than the absurd horse-power that has become so rooted among our engineers. A man in pumping expends about 50 watts; in rowing a race he expends about 100; in running rapidly upstairs he expends 500 watts for a few seconds; a horse drawing a load on a level road expends about 500 watts. The so-called horse-power is 746 watts. An ordinary arc lamp consumes 500 watts, and an electric tramcar going at seven miles an hour on an average tramway, requires a mean power of about 3,000 watts.

Electrical energy is measured and paid for in 1,000 watts or in *kilowatts* delivered per hour. A kilowatt-hour is called the Board of Trade unit of electrical energy, and it is defined in all Provisional Orders confirmed by Act of Parliament, thus:—"The expression 'unit' shall mean the energy contained in a current of one thousand amperes flowing under an electromotive force of one volt during one hour." This Board of Trade unit has not yet received a name. I have proposed to call it a *Bot*, from the initial letters of the Board of Trade, but there is generally a very strong aversion to a new name, however much it may be wanted, and we have during the past few years had a plethora of new names in electrical science. One Board of Trade unit will keep an ordinary 10-candle power glow-lamp alight for 30 hours, or it will keep 30 of such lamps alight for one hour. In Newcastle this energy costs 4½d., in Liverpool 6d., in London 7½d., and in most other places 8d. Taking the cost at 6d., a 10 candle-power glow-lamp would cost one-fifth of a penny per hour, which is the cost of a 5ft. gas burner at 3s. 4d. per 1,000 cubic feet. There is thus very little difference between the price of gas and that of electricity.

The output of a dynamo is measured in watts, and, as the number of watts in ordinary dynamos is necessarily numerous, the *kilowatt*, or 1,000 watts, is the unit employed. Thus, a dynamo of 100 kilowatts developes energy equivalent to 134 horse-power, and as, for ordinary purposes, the ratio of the power utilised as electric current to the power indicated in the cylinders of the engine may be taken at 80 per cent., it will follow that it will require 160 horse-power to drive such a dynamo at full load. The relations between mechanical and electrical measurements are thus very simple and wonderfully accurate. 100 kilowatts, or 100,000 watts, deliver sufficient energy to illuminate 3,000 10 candle-power lamps, and one of the most difficult problems which the electrical engineer has to solve is to design the best and most economical method of distributing this energy over an extended area. If the distribution be confined to one big building, like the Pavilion in Brighton, or the Post Office in London, the solution is simple. If it be over a widely scattered district, like Croydon, Wimbledon, or the districts of the great vestries of London, the solution is complicated. Every district must be governed by its own conditions, and be controlled by its own environments.

There are several modes of distribution under high pressure or low pressure; by means of alternate currents or of continuous direct currents; by two wires or three wires or five wires. Then, again, the supply may be for light or motive power, for street lighting, or for private lighting. If it be by high pressure, say of over 300 volts, then, as such pressures cannot be admitted into our houses, there must be a reduction of this pressure to the safe and ordinary 100 or 50 volts by means of alternating transformers or of secondary batteries. The ruling guide is of course economy. A certain number of kilowatts are generated in the central station, at a price per hour that is easily obtained from the coal bills, the stores list, and the wages sheet. A certain proportion of this energy is delivered to the consumers, and paid for by them by meter or by contract. A certain proportion is lost: wasted as heat in the apparatus and conductors. What is the proportion between the energy paid for, and that generated by the central station? What is, in fact, the efficiency of the system? It is difficult in the present tentative and youthful condition of the industry to obtain a true answer. Most central stations are in their pioneer condition. I have, however, examined the figures of certain well-known systems, from which I gather that we may estimate the following efficiencies as fairly practical:—

	Efficiency.
Low pressure—	
Continuous direct current	90 per cent.
High pressure—	
Alternate current	60 ,,
Direct-current battery	50 ,,

In fact, one Company—the St. James and Pall-mall—working on the low-pressure system, have on the first half-year of 1890 secured a return of 94·3 per cent. on the energy delivered, while another Company, working on the high-pressure battery system, secured only 29 per cent. In January of this year, at the Kensington Court Central Station, working at low pressure, 25,893 bots were registered and paid for, as against 28,291 generated and distributed, representing an efficiency of 92 per cent. At Dacre-street, Westminster, also working at low pressure, in the quarter ended 24th June—the summer and lowest quarter—the efficiency was 84·4 per cent. At the House of Commons the efficiency has been 89·8 per cent. A simple way of looking at the matter is to find out the coal consumed per bot paid for by the consumer. It comes out—

Low pressure	9lb.
High pressure	17lb.

It is worth noting that it would require 38lb. of coal distilled in the gas works to produce the same light by means of the ordinary fish-tail burner.

The misfortune is, that the low-pressure system is applicable only to confined and restricted districts. It involves the use of such heavy conductors, that as the district increases in extent, the weight of copper required varies as the third power of the radius of the area served. While with the high-pressure system the weight of copper required diminishes with the pressure used. It must, however, be recollected that the use of high pressure involves the use of very highly insulated conductors, and therefore what is saved in copper may be expended in insulation. The question that decides the economic use of high or low pressure is the distance or length of mains and feeders, when the difference between 17lb. and 9lb. of coal (or a penny per bot) is swallowed up in interest on capital and waste of energy in the heavy conductors required by the low-pressure system.

The consequence is, that while compact areas, covered by a radius of half a mile, are best served on the low-pressure system, those supplied beyond a radius of one mile can be served economically only on the high-pressure system, while the intermediate range is to be considered simply with reference to its own requirements and its own conditions, such as the supply of water and of coal, the convenience of water and railway carriage, the value of land, the demand of residential districts, and of manufacturing and business quarters. Each district must therefore be dealt with on its own merits. In London at the present moment several different systems are being used or installed for very similar districts. Thus we have the alternate-current transformer system at Brompton, St. Martin's, St. Giles, and the various portions served by the London Electric Supply Association, the high-pressure battery system in Chelsea, the low-pressure system aided by secondary batteries to regulate pressure and to maintain the supply of energy during the small hours of the morning, or when breakdown or cases of emergency arise, in Kensington, Westminster, St. James's, Notting Hill, and St. Pancras. The proper system to be used is therefore still in a tentative condition.

The great question that divides the merits of the high and low-pressure is that of safety to person. Grossly exaggerated accounts of accidents in America have seriously prejudiced the public mind against the high-pressure system. If people only saw for themselves the conditions that surround the distribution of electricity in the United States, they would not be surprised at the accidents that have happened—they would wonder at their being so few. Poles are frequently carried down the principal streets of the towns carrying open telegraph, telephone, fire signal, and electric light wires, all together on the same support, without any particular rules or regulations. A lineman who ascends a pole to attend to a telephone wire is very apt to touch suddenly an electric light conductor. He receives a shock, and is thrown down perhaps on the ground and killed, or perhaps among the other wires, where he may be probably burnt or otherwise injured.

Such things are impossible in England. Mains and conductors must, by legislation, be placed underground in all towns; but where they are for local reasons placed overground, they are subjected to carefully prepared rules and regulations, and to watchful and constant inspection. A high-pressure conductor is certainly dangerous if it were handled; but it should never, under any circumstances, be so placed as to be in a position to be touched by anyone but the skilled technical men who have the charge of its maintenance. There is no case on record of anyone being hurt on a well-designed underground system.

The great hygienic advantage of the electric light when illuminating our dwellings and our workshops is not that it purifies the air, but that it prevents the air from being vitiated by the introduction into it of the products of combustion, such as carbonic acid, carbonic oxide, sulphurous acid, &c., it prevents the air from being weakened by the abstraction of oxygen, and it prevents it from having its temperature raised by undue radiation, and by throwing into it heated gases.

While legislation and the greatest possible stringent regulations have been drawn up to prevent the adulteration of food and the poisoning of water, scarcely any attention has been devoted to the prevention of the admission of noxious gases and poisonous vapours into the air of our habitations. Carbonic oxide is a poison of the

Digitized by Google

deadliest character, and gas jets are freely used which deliver copious discharges of this dangerous gas into the atmosphere of our rooms. If we were consistent in our legislation, we ought to forbid the use of any burner which thus poisons the air. A man at rest exhales ·00424 cubic feet of carbonic acid gas (CO_2) and ·1189 cubic feet of air per pound weight per hour, while a gas jet burning 5 cubic feet of coal gas exhales 4 cubic feet of CO_2. The maximum proportion of CO_2 to air consistent with health is 6 volumes in 10,000; 10 volumes affect the heart, and 30 volumes produce headaches. Rheumatism, bronchitis and other ailments proceed from higher proportions. In fact, 5 cubic feet of gas requires 8,000 cubic feet of pure air per hour to maintain it healthy. The electric light requires no such provision.

That the electric light is a powerful element of health is evidenced by the fact that those who use it not only feel all the better for its introduction, but their appetite increases, and their sleep improves, and the visits of the doctor are reduced in frequency. Workpeople work all the better, and absences from illness are far less frequent. In the Savings Bank in Queen Victoria-street, London, where 1,200 persons were employed, the absences from illness were so far reduced that the extra labour gained paid for the electric light. In Liverpool and many other places the same result has been observed.

The influence of artificial light on the eyes has a very important sanitary bearing. Why is it that there is so much shortsightedness in the present day? Is it due to our mode of producing light? Some assert that the injury to the eyes is due to the heat rays and not the light rays. If that be so, the electric light must be much less injurious than any other. On the other hand, no one can have experimented with arc lamps without having had his retina painfully affected, which leads one to think that the ultra-violet rays have some influence. No one has, however, ever complained of the influence of a steady glow-lamp upon the eyes, and it is possible to read and to write for many hours by such a light without experiencing the least fatigue.

The electric current is not altogether free from being a cause of fire, and though its use is by no means very general, still it is used sufficiently to make itself felt as an element of danger in this respect. The following table shows the number of fires in London which can be traced to the different methods of lighting:—

	1887.	1888.	1889.	Total.
Lamps	245	205	257	707
Gas	188	197	209	594
Candles.....	142	113	136	391
Electricity	0	1	2	3

The progress of the electric light in our homes has been much more rapid in England than in any other country, but its employment for street lighting, for shops and manufactories, has been infinitely more rapid and extensive in the United States than with us. In America the growth has been enormous. There are now 250,000 arc lamps, illuminating the public streets and shops, and 3,000,000 glow lamps in dwellings, stores, and workshops.

The following table shows the development of the Berlin Central Stations:—

Station.	Effective horse-power.						
	1884.	1885.	1886.	1887.	1888.	1889.	When completed.
Friederickstrasse..	300	300	300	300	300	300	300
Markgrafenstrasse	...	1,000	1,000	1,000	2,400	2,400	3,100
Mauerstrasse	...	...	500	1,250	1,250	2,950	4,950
Spaudauerstrasse..	...	...	...	...	...	2,000	4,000
Schiffbauerdamm.	...	...	...	...	...	1,000	6,000
Total	300	1,300	1,800	2,550	3,950	8,650	18,350
16 c.p. lamps, or equivalent	2,500	4,600	13,229	24,660	34,750	...	...
Kilometres of cable	...	8	10	15	25	75	...

The progress in England has been very much checked by inordinate speculation and by terrible failures in some of the earlier work done. There is something very captivating in the practical applications of electricity, and something romantic in its mystery. The neophyte has rushed into it with remarkable fervour, and the lessons of failure have in consequence been very severe. The users of the light have also been paying heavily for the education and experience of amateur tradesmen and inexperienced contractors, and have neglected to avail themselves of the professional services of the experienced electrical engineer. People who would not build houses without the architect, nor construct bridges without the engineer, nor make their wills without the lawyer, rush wildly into the use of electricity without any professional assistance, where, above all things, experience and knowledge are essential to prevent disaster and disappointment. Large installations have been completed without specifications to guide the contractor, and without inspection to see that the work has been properly done. The user has paid violently for his temerity, and fires and accidents have been the result. The heavy price for wiring a rented house, and the expensive character of the fittings proposed, have deterred many from adopting the light, even when it is within their reach. Highly insulated wire is unfortunately expensive. All cheap wires are nasty and dangerous. There is nothing that becomes the electric light better than simplicity, and its effect is frequently marred by elaborate brass work. It possesses also most active and widespread opponents, both in oil and gas—opponents who have benefited by its introduction, and who are not slow to profit by its advance. The improvements in gas and oil lamps are as marked as the advancements in electric light, and as means of artificial illumination alone—that is as far as light-giving power is concerned—there is little choice between the three; but oil and gas cannot lose those elements of discomfort and ill-health which differentiate them from the cool and pure glow lamp.

A very important question arises for discussion. Legislation has slipped in to place the virtual control of the supply of electrical energy in the hands of the Local Authority of the district to be served. Is this supply to be the result of the capital of private enterprise, or is it to be effected by raising money on the security of the rates? It is argued that the supply of electricity being a purely commercial undertaking, it should therefore be carried out by a limited liability company. The Acts of 1882 and 1888 do not encourage monopoly, but rather court competition, and competition attracts capital. Competition properly regulated and controlled secures economy in supply, and certainly enforces economy in working, while it encourages improvements, and induces perfection of apparatus and novelty in processes. These arguments are plausible, but are easily refuted by those who desire to uphold vested monopolies. Direct competition always means ultimately enhanced cost to the public, for the same public has to pay for double plant, and each competitor only gets half revenue.

The supply of light is in precisely the same category as the supply of water or the supply of gas, and the days have certainly passed when the public will tamely submit to the transference of their right to such vested interests as those of water or gas companies. It is very easy to argue *pro* or *con.* on each side. The Local Authority has to regard the security of traffic, the safety of person, the repression of crime, and the proper supervision of the premises of its ratepayers. It is the custodian of the public interests. It has to control the health, cleanliness, comfort, and beneficial sanitation of its habitable dwellings. It, therefore, must secure the best light, and if it can do this, and at the same time relieve the rates which are generally creeping up to dangerous dimensions, then its action would be wise and economical. But it would be entering into commercial rivalry with an active competitor—the gas companies; and its commercial control by such a shifting authority as a committee of a Town Council or of a Local Board, subject to the changes of political warfare—to the vagaries of press dictation, and to the fear of November elections—is a very doubtful proceeding. On the other hand, in many instances, such bodies have successfully dealt with the water question, the tramways, and even with the gas. In fact, one-third of the gas capital (21 millions) in this country is in the hands of 173 Local Authorities, and more than half a million of profits go to the reduction of rates.

Bradford has already grappled with the question. It has established a central station for the supply of the electric light. Brighton, St. Pancras, and Bristol are doing the same, and many other places are following suit. They are shying at the probability of handing over their districts to a speculative company, with a virtual, though not a legal monopoly, to supply electrical energy for 42 years. Many corporations contemplate a middle course. They have obtained the power for themselves, but they have farmed for shorter terms the right of supply to private enterprise, which can do what they are afraid to do, viz.—speculate and experiment. The Board of Trade has sanctioned and facilitated such a transfer of statutory rights.

It is surprising that gas administrations in England have not been more enterprising in developing electric lighting. In Vienna, Rome, and Stockholm the gas companies have established central stations, and the progress of the industry in those cities is very great. The proper function of gas is to supply heat, not light; and as a source of power it has a future more brilliant than its past. If it could be supplied as fuel, it would remove the troubles of coal transit and storage, of ash and dust removal, of smoke and of stoking. It has even been shown that it is cheaper to convert coal into gas on the spot, and to use the gas as the source of power, than to apply the coal direct for the production of steam in boilers.

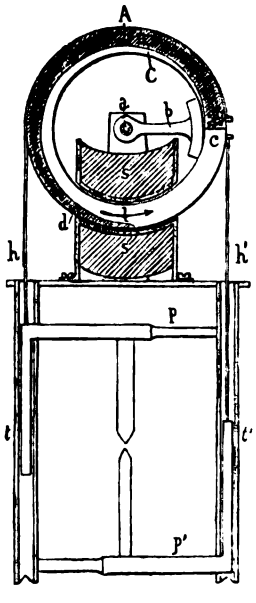
Digitized by Google

The waste of energy in the use of coal is enormous. The energy contained in one pound of coal if burnt in one hour is theoretically sufficient to supply 5·6 horse-power for that hour. The best practical result yet obtained by the steam engine is scarcely one horse-power. The electric light is unquestionably the light of the future. Its use is advancing with leaps and bounds. Not only is it naturally the proper source of light, but economically it must eventually supplant its rivals. When electrical energy is generally distributed through our towns, and its supply is continuous, and properly controlled, so that it is always within the reach of all, and when means can be devised to wire up houses as cheaply as they are now fitted for gas, everyone will take it, not alone for its beauty, but because it is, above all, a source of health and comfort.

THE ZWEIFEL ARC LAMP.

This lamp, which was exhibited at the Paris Exhibition of 1889, is of very simple construction. It consists of a ring of iron or copper, moving inside a solenoid, working the carbon holders by means of two small chains, and thus striking the arc and supplying the feed.

The ring A is composed necessarily partly of iron, the section of which increases from d to e, and is carried by the arm b; the remaining portion of the ring consists of brass, the two metals being so proportioned that perfect equilibrium is obtained between them about the axis a. To the ring are attached two small chains, $h\,h'$, from which are suspended the carbon holders $p\,p'$, which are guided by a special arrangement inside the tubes t and t'. The lower carbon holder p' is heavier than the



The Zweifel Arc Lamp.

upper carbon holder p, and consequently tends to separate the carbons, and bring the ring into its extreme position as shown in the diagram. When a current passes through the solenoid, it tends on the other hand by reason of its action on the iron of the ring to move it in the direction of the arrow l, and to bring the carbons together. The solenoid is a fine wire coil, and is connected as a shunt to the two carbon holders. It governs, therefore, the potential difference between the two carbons, or, in other words, the distance of the two carbons from each other. By keeping this distance constant we obtain a steady light, the intensity of which may be regulated by means of a suitable rheostat.

The mode of working is as follows:—When no current passes through the apparatus, the extra weight of the lower carbon p', acting on the small chain h', causes the ring to turn from left to right, and to bring it into the extreme position represented in the diagram, and consequently to separate the carbons; but when the lamp is placed in connection with a source of electricity, the current will be unable to pass through the carbons, which are separated, but will go through the solenoid, and the latter will act energetically on the iron portion of the ring. This ring then moves from right to left, the upper carbon falls and the lower one rises, this movement continuing until the carbons touch. When the carbons are in contact the whole current passes through them. The coil, no longer receiving any current, will exert no force upon the ring. The extra weight of p' acting on the ring will produce a movement in the opposite direction, the two carbons being drawn apart, and the arc struck. As the arc lengthens the current encounters more and more resistance in its passage through the carbons, and more current will pass through the solenoid, which thus becomes more powerful as the arc becomes longer.

The two opposing forces in this case are—

(1) The attraction due to the coil, which increases with the length of the arc.

(2) The difference in the weights of the carbon-holders.

Equilibrium exists when the attractive force is equal to the force due to the difference in the weights of the carbon-holders. The attractive force being a function of the length of the arc, it is easy to understand that one has only to regulate the difference in weight in order that the solenoid may maintain any desired length of arc. It is only necessary that the ratio of the attractive force to the difference between the weights of the carbon holders should be the same for all positions of the ring for the lamp to constantly maintain the same distance between the carbons.

The above arrangement is usually employed for lamps run on incandescent light circuits; for use in series working a lamp with a differential action is used. It is said that the light given by this lamp is very steady, the feeding being very rapid and continuous. The lamps may be worked either singly or in pairs on incandescent light circuits, working with a resistance which only absorbs, it is stated, from 15 to 20 per cent. of the energy supplied to the lamp, whilst most lamps at present in use waste in the resistance about 40 per cent. of the total energy supplied. Amongst the advantages that this lamp possesses are a fixed focus, compactness, and freedom from complicated mechanism.

THE NEW BOARD OF TRADE REGULATIONS.

The following are the Regulations and Conditions for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy, made by the Board of Trade under the provisions of the Electric Lighting Acts, 1882 and 1888, and of the Notting Hill Electric Lighting Order, 1889:—

Definitions.

In the following regulations:—

The expression "the order" means the Notting Hill Electric Lighting Order, 1889.

The expression "the undertakers" means the undertakers for the purpose of the order.

The expression "consumer" means any body or person supplied or entitled to be supplied with energy by the undertakers.

The expression "consumer's terminals" means the ends of the electric lines situate upon any consumer's premises and belonging to him at which the supply of energy is delivered from the service lines.

The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the undertakers at the consumer's terminals.

The expression "aerial conductor" means any conductor which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; pressure on any alternating-current system being taken to be the equivalent of pressure on a continuous-current system when it produces an equal heating effect if applied to the ends of a thin stretched wire or carbon filament; and

(*a*) Where the conditions of the supply are such that the pressure cannot at any time exceed 300 volts, if continuous, or the equivalent of 150 volts, if alternating, the supply shall be deemed a low pressure supply;

(*b*) Where the conditions of the supply are such that the pressure may exceed the limits of a low-pressure supply, but cannot exceed 3,000 volts, or the equivalent of 3,000 volts, whether continuous or alternating, the supply shall be deemed a high-pressure supply;

(*c*) Where the conditions of the supply are such that the pressure may on either system exceed 3,000 volts or the equivalent of 3,000 volts, the supply shall be deemed an extra high-pressure supply.

Mains, service lines, and other conductors and apparatus are referred to as low-pressure, high-pressure, and extra high-pressure mains, &c., according to the conditions of the supply delivered through the same or particular portions thereof.

Provided that in the case of conductors laid under the surface of the ground in conduits, in accordance with these regulations, and being the property or under the sole charge of the undertakers, low pressure conductor shall mean any conductor in which the pressure between that conductor and the earth cannot at any time if continuous exceed 300 volts, or if alternating, 150 volts, or between that conductor and any other conductor laid in the same conduit cannot at any time if continuous exceed 500 volts, or if alternating, 250 volts.

When any casing, support for conductors, conducting wire, or other metallic body is required to be efficiently connected to earth, it shall be deemed to be so connected when it is connected to metallic mains for water supply outside of buildings, or, where these are not available, to a

Digitized by Google

mass of metal having a total surface of at least four square feet, buried to a depth of at least three feet in moist earth, by means of a conductor possessing a mechanical strength, and offering a passage to electrical discharges, equal to that of a strand of seven No. 16 galvanised iron wires.

The expression "daily penalty" means a penalty for each day on which any offence is continued after conviction thereof.

All other expressions to which meanings are assigned in the Order, or principal Act, have the same respective meanings in these regulations.

I.—Regulations as to Safety.

General.

1. *Low-Pressure Supply to Consumers.*—Save as hereinafter provided, the supply of energy delivered to the consumer's terminals shall be a low-pressure supply.

2. *Limitations of High-Pressure Supply.*—A high-pressure supply shall not be delivered to any consumer's terminals, except for special purposes, and with the approval of the Board of Trade on the joint application of the consumer and the undertakers, and subject to such further regulations as the Board of Trade may from time to time prescribe. But a high-pressure supply may be given to distributing or converting stations or points, or to distributing mains, in accordance with the following regulations.

3. *Limitations of Extra High-Pressure Supply.*—An extra high-pressure supply shall not be given except to distributing stations or other premises in the sole occupation of the undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board may prescribe.

Mains and other Conductors.

4. *Maximum Current in Conductors.*—The maximum working current shall not be sufficient to raise the temperature of the conductors or any parts thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30° of Fahrenheit's thermometer; and efficient automatic means shall be provided which will render it impossible for this maximum working current by any accident to exceed such limit to the extent of 50 per centum, even for short intervals of time; and special care shall be taken that the cross sectional area and conductivity at joints are sufficient to avoid local heating, and that the joints are protected against corrosion.

5. *Lightning Protectors.*—Where any portions of any conductors are exposed in such a position as to be liable to be affected by lightning, they shall be efficiently protected against accident by appliances of such pattern and construction as may from time to time be approved by the Board of Trade.

6. *High-Pressure Conductors Laid Above Gound.*—Where any high-pressure conductors, other than aerial conductors, are placed above the surface of the ground, they shall be completely enclosed in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected to earth.

7. *High-Pressure Conductors Laid in Subways, &c.*—Where any high-pressure conductors are laid in subways, or in the same conduits with any low-pressure conductors, they shall be completely enclosed in strong metal casing efficiently connected to earth.

8. *High and Low Pressure Conductors Laid in Proximity.*—Where any high-pressure conductor is laid within a less distance than 18in. for any low-pressure conductor, or from the surface of the ground, or where any low-pressure conductor is laid within the above-mentioned distance from any previously laid high-pressure conductor, efficient means shall be taken to render it impossible that the low-pressure conductor or the surface of the ground shall become electrically charged by any leakage from or defect in the high-pressure conductor.

9. *Continuous Insulation.*—Every high-pressure conductor shall be continuously insulated with a durable and efficient material, which shall be protected on the outside against injury or removal by abrasion, and every such conductor shall be tested for insulation after having been laid in position, and before any joints for service lines are made. The insulation resistance under these conditions shall not be less in any section of the conductor than at the rate of 100,000 ohms per mile for every volt of pressure of the supply under a testing pressure of at least 100 volts, and the undertakers shall duly record the results of the tests of each conductor or section of a conductor, and at all times permit an electric inspector to examine and take copies of such record.

10. *Minimum Insulation Resistance Allowable; Indicator of Leakage.*—The insulation resistance of any complete circuit used for high-pressure supply, including all devices for producing, consuming, or measuring energy, connected to such circuit, shall be such that should any part of the circuit be put to earth through a resistance of 2,000 ohms, the leakage current shall not exceed 0·04 ampere in the case of continuous currents, or 0·02 ampere in the case of alternating currents. Every such circuit shall be fitted with an instrument of such pattern and construction as may from time to time be approved by the Board of Trade, which shall immediately indicate any defect which may at any time occur in the insulation resistance of either conductor.

Every such circuit shall be tested for insulation at least once in every week, and the undertakers shall duly record the results of such testings, and at all times permit an electric inspector to examine and take copies of such records.

11. *Precautions against Sparking with High Pressure Alternating Current Mains.*—In the case of a high-pressure supply on any alternating-current system, where separately insulated conductors are laid in the same conduit, or pass through the same boxes, precautions shall be taken against the discharge of electric sparks between the insulating covering of oppositely charged conductors, by providing a sufficient connection of a conducting nature from one covering to the other throughout.

Conduits.

12. *Conduits to be Durable and Strong.*—All conduits used as receptacles for conductors shall be constructed of durable material, and of ample strength to resist any pressure due to heavy traffic or other forces to which they may be expected to be subjected.

13. *Conduits to be Kept Free from Water.*—Where the conductors in any conduit are not continuously insulated, adequate precautions shall be taken to insure that no accumulation of water shall take place in any part sufficient to raise the level of the water into contact with the conductors.

14. *Conduits to be Kept Free from Gas.*—All conduits for conductors constructed in streets in which gas mains are also laid, shall be efficiently protected against an accumulation of gas.

15. *Street Boxes to be Kept Free from Gas and Water and Secured.*—All street boxes shall be efficiently protected against an accumulation of gas or water, and their covers so secured that they cannot be opened except by means of a special appliance.

Converting Stations.

16. *Converting Stations.*—Converting stations, or points in a system of distribution to which a high-pressure supply is given from generating stations, and from which a low-pressure supply is given to one or more consumers, and which are not on the consumer's premises, shall be established in suitable places, which are in the sole occupation and charge of the undertakers.

17. *Precautions against Contact.*—In every case where the supply is transformed at a converting station as described in the preceding regulation, some means or apparatus approved by the Board of Trade shall be provided which shall render it impossible that the low-pressure distributing mains shall be at any time charged to a dangerous difference of potential from the earth, owing to any accidental contact with, or leakage from, the high-pressure system either within or without the converting station.

Consumers' Premises.

18. *Transformers and High-Pressure Apparatus to be Enclosed in Metal.*—Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on the consumer's premises, connected to the distributing mains by high-pressure service lines, and to the consumer's terminals by low-pressure service lines, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself, so far as they shall be on the consumer's premises, shall be completely enclosed in solid walls, or in strong metal casing efficiently connected to earth, and securely fastened throughout.

19. *Precautions against Contact.*—In every case where any transforming apparatus is installed on the consumer's premises, as described in the preceding regulation, some means or apparatus approved by the Board of Trade shall be provided, which shall render it impossible that the low-pressure service lines and consumer's wires shall be at any time charged to a dangerous difference of potential from the earth, owing to any accidental contact with, or leakage from, the high-pressure system either within or without the transformer.

20. *Low-Pressure Apparatus to be Insulated.*—All terminals, low-pressure service lines, or other apparatus, between the transforming apparatus or other source of supply and the consumer's terminals, so far as they shall be on the consumer's premises, shall be completely enclosed in insulating cases or coated with insulating material in such a manner that no part of them can be touched by any person without the removal of such case or coating, and, wherever exposed, shall be efficiently protected against injury to the insulation.

21. *Responsibility of Undertakers for their Lines, &c., on Consumer's Premises.*—The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon the consumer's premises being maintained in a safe condition, and in all respects fit for supplying energy.

22. *Fire Risks.*—In delivering the energy to the consumer's terminals, the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

23. *Testing Consumer's Wires for Leakage by Undertakers.*—If the undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a connection with the earth exists at some part of a circuit, of such resistance as to be a source of danger, and that such connection does not exist at any part of the circuit belonging to the undertakers; then, and in such case, any officer of the undertakers, and duly authorised by them in writing, may, for the purpose of discovering whether such connection with the earth exists at any part of a circuit within, or upon, any consumer's premises, at all reasonable times, after giving one hour's notice of his intention to do so, enter any such premises and disconnect the consumer's wires from the service lines, and may require the consumer to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit.

24. *Supply to be Discontinued.*—If on such testing the officer discovers that a connection exists between the consumer's wires and the earth, and that such connection has an electrical resistance not exceeding 5,000 ohms, or if the consumer does not give all due facilities for such inspection and testing, the undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of such discontinuance to the consumer, and shall not recommence such supply until they are reasonably satisfied that such connection with the earth has been removed.

Digitized by Google

Provided that in cases where the maximum power taken by any consumer exceeds 25,000 watts, the consumer's wires may be divided for the purposes of this testing into separate circuits, the insulation resistance of each of which shall exceed 5,000 ohms.

25. *Appeal to Electric Inspector.*—If any consumer is dissatisfied with the action of the undertakers either in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of such consumer may, on his application, and on payment of the prescribed fee, be tested for the existence of connection with the earth by an electric inspector, or if no electric inspector has been appointed, by a person appointed by the Board of Trade.

This regulation shall be indorsed on every notice given under the provisions of the last preceding regulation.

Regulations as to Aerial Conductors where Erected with Necessary Consents.

26. *Height from Ground and Distance from Buildings, &c.*—An aerial conductor shall not in any part thereof be at a less height from the ground than 20ft., or where it crosses a street 35ft., or within 7ft. of any building or erection other than a support for the conductor, except where brought into a building for the purpose of supply.

27. *Service Lines from Aerial Conductors.*—Service lines from aerial conductors shall be led as directly as possible to insulators firmly attached so some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment to the consumer's terminals they shall be enclosed and protected in accordance with the preceding regulations as to service lines on the consumer's premises.

28. *Maximum Intervals between Supports.*—Every aerial conductor shall be attached to supports at intervals not exceeding 200ft. where the direction of the conductor is straight, or 150ft. where this direction is curved, or where the conductor makes a horizontal angle at the point of support.

29. *Supports, Construction and Erection of.*—Every support of aerial conductors shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the conductors, or unequal lengths of span, and the conductors and suspending wires (if any) shall be securely attached to insulators fixed to the supports. The factor of safety for the conductors and suspending wires shall be at least six, and for all other parts of the structure at least twelve, taking the maximum possible wind pressure at 50 pounds per square foot. No addition need be made for a possible accumulation of snow.

30. *Connection of Support to Earth.*—Every support, if of metal, shall be efficiently connected to earth, and if of wood or other non-conducting material, shall be protected by a lightning conductor fastened to the support along its entire length, and projecting above the support to a height of at least six inches, such lightning conductor being efficiently connected to earth.

31. *Angle of Crossing Thoroughfares.*—Where any aerial conductor crosses a street, the angle between such conductor and the direction of the street at the place of such crossing, shall not be less than 60 degrees, and the spans shall be as short as possible.

32. *Crossing Other Wires.*—Where any aerial conductor belonging to the undertakers is erected so as to cross any other aerial conductor or any suspended wire used for purposes other than the supply of energy, precautions shall be taken by the undertakers against the possibility of their conductor coming into contact with such other conductor or wire, or of such other conductor or wire coming into contact with their conductor by breakage or otherwise.

33. *High-Pressure Conductors to be Insulated.*—Every high-pressure aerial conductor shall be continuously insulated with a durable and efficient material to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch; and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. This insulation shall be further efficiently protected on the outside against injury or removal by abrasion. If this protection be wholly or partly metallic it shall be efficiently connected to earth.

34. *Specification of Insulation.*—The material used for insulating any high-pressure aerial conductor shall be such as will not be liable to injurious change of physical structure or condition when exposed to any temperature between the limits of 0° and 150° Fahr., or to contact with the ordinary atmosphere of towns or manufacturing districts.

35. *Suspension of Conductors.*—Every aerial high-pressure conductor shall be efficiently suspended by means of non-metallic ligaments to suspending wires, so that the weight of the conductor does not produce in it any sensible stress in the direction of its length, and the insulated conductors and suspending wires, where attached to supports, shall be in contact only with material of highly insulating quality, and shall be so attached and guarded, that in case they break away it shall not be possible for them to fall away clear of the support.

36. *Undertakers Responsible for Supports.*—The undertakers shall be responsible for the efficiency of every support to which their aerial conductors are attached, and every such support shall be marked to indicate the ownership of the conductor.

37. *Maintenance.*—Every aerial conductor belonging to the undertakers, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with it, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

38. *Unused Conductors to be Removed.*—The undertakers shall not permit any aerial conductor to remain erected after it has ceased to be used for the supply of energy, unless they intend within a reasonable time again to take it into use.

39. *Penalties.*—If the undertakers make default in complying with any of the preceding regulations they shall be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10.

The imposition of any penalty under this regulation shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of such default.

II.—*Regulations as to Supply.*

1. *Notice of Intention to Supply Through Mains.*—One week at least before the undertakers are ready to commence to supply energy through any feeding, charging, or distributing mains, they shall serve a notice upon the County Council and the local authority of their intention to commence such supply.

2. *Undertakers to Provide Constant Supply.*—From and after the time when the undertakers commence to supply energy through any distributing mains, they shall maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main; and such supply shall, except so far as may be otherwise agreed upon from time to time between the County Council and the undertakers, be constantly maintained at such pressure as may be fixed under the provisions of these regulations. Provided that, for the purposes of testing, the authority by whom the electric inspector is appointed may give permission to the undertakers to discontinue the supply at such intervals of time and for such periods as it may think expedient, and that for any other purposes connected with the efficient working of the undertaking, the undertakers may, with the permission of the Board of Trade, discontinue the supply at such intervals of time and for such periods as the Board of Trade may think expedient. Where the supply is so discontinued notice of such discontinuance, and of the probable duration therof, shall be forthwith served upon the County Council and the local authority.

3. *Maximum Supply from One Section of Main.*—The system of distributing mains shall be so arranged in sections, that in case it becomes necessary to stop the supply through any portion of a main for more than one hour, for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than 80 consumers, and in the case of every stoppage for more than one hour reasonable notice shall be previously given by the undertakers to every consumer affected thereby except in cases of emergency.

4. *Pressure in Mains during Supply.*—During the whole of the period when a supply of energy is required to be maintained by the undertakers in the distributing mains under the order and these regulations, it shall be maintained at a constant pressure (in these regulations termed "the standard pressure") to be fixed as hereinafter specified; but such standard pressure may be different for different portions of the distributing mains. Provided that the undertakers shall be deemed to have complied with the requirements of this regulation so long as the pressure does not at any point vary more than 3 per cent. from the corresponding standard pressure, in the case of a general supply at low pressure, or 2 per cent. in the case of a general supply at high pressure, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

5. *Fixing of Standard Pressure.*—The standard pressure shall be fixed by the undertakers for every pair of distributing mains, and notice of the amount of such standard pressure shall be given to the County Council before the undertakers commence to supply energy to consumers through such mains, and such standard pressure shall not be altered except by permission of the County Council, and upon such terms and conditions as the County Council may impose, and after public notice has been given during a period of one month, in such manner as the County Council may require, of the intention of the undertakers to apply for permission to alter the same. The undertakers may appeal against any decision of the County Council under this regulation to the Board of Trade, whose decision shall be final.

6. *Declared Pressure at Consumer's Terminals.*—Before commencing to give a supply of energy to any consumer, the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not, except by agreement, be greater than 115 volts or less than 45 volts, if continuous, or the equivalents thereof respectively, if alternating, and shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In distribution on the three-wire system, the central terminal shall for the purposes of this regulation be considered to form a pair with either of the outer terminals, and similarly for multiple-wire systems; and, in the case of a transformation of energy on the consumer's premises, the undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

7. *Variation of Pressure at Consumer's Terminals.*—The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, nor at any time, exceed four per centum from the declared constant pressure, whether such variation be due to the resistance of the service lines or apparatus belonging to the undertakers, or to any action or effect produced by such apparatus, for which the consumer cannot be shown to be responsible, or, partly to any variation of pressure in the distributing mains from which the supply is taken.

Digitized by Google

8. *Penalty for Default.*—If the undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the Order, be liable to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

These regulations are made subject to the power of the Board of Trade to make such further or other regulations as they may think expedient; and nothing in these regulations shall be construed to authorise the undertakers to lay any electric line or work their undertaking otherwise than in accordance with the Order and the principal Act, or to supply energy otherwise than by a system for the time being approved of by the Board of Trade under the Order.

ON THE EXPERIMENTS OF HERTZ.*

BY L. BOLTZMANN.

I have successfully demonstrated to a large audience the sparks which pass between a knob and a point in Hertz's experiments on rays of electrical force, by connecting the knob with a very sensitive electroscope, and the point with the pole of a suitable galvanic battery the other pole of which was put to earth. As long as there were no minute sparks or *scintillæ* the electroscope remained uncharged; but when these were formed they established a connection between the knob and the point and caused the leaves to diverge. In this manner I was able to show with certainty the scintilla produced by a single primary spark when the primary and secondary inductors were at a distance of 36·8 metres apart, the greatest distance available.

At a distance of 8·7 metres all the Hertz experiments could be most conveniently demonstrated before an audience of about 200, so as to be visible to every one; only three or four primary sparks were required for each experiment, by which the electrodes could be kept brightly polished. Dust, cracks in the metal, or an impure greasy condition of the surface, appeared more injurious than the layer of oxide: cleaning with dilute sulphuric acid, distilled water, and then dry rubbing was found to be best; a thicker layer of oxide is removed by polishing with French chalk (moistened with spirit), in which case dry rubbing is sufficient. I was not able to perceive any advantage in a current of air as recommended by Dr. Classen.

The length of the secondary spark produced at the great distance of 36·8 metres I estimated at $\frac{1}{3000}$ millimetre as the maximum. As the dry pile which served to charge the electroscope had a potential of 200 volts, the knob and the point were adjusted at a distance which exceeded by about $\frac{1}{3000}$ the striking distance of the dry pile, the discharge of which was then set up by the addition of Hertz's waves to the tension of the dry pile. By using a much more feebly charged battery instead of the dry pile, and a much more delicate galvanoscope, Hankel's for example, the rays might be perceived at still greater distances. In the latter case it might not be impossible to measure the deflexion with a view to quantitative determinations. The regulation of the distance between the knob and the point must then be made so much the finer.

I also made experiments on interference by reflecting the waves from the primary parabolic mirror through two plane mirrors, which, like those of Fresnel, formed an obtuse angle, and whose planes were at a distance of fourfold a half wave-length. This method seems well suited for accurate measurements of the wave-length and of the decrement of the vibration.

AN EASY MODE OF PRODUCING THE ACTIVE SPARK IN HERTZ'S EXPERIMENTS.*

BY H. CLASSEN.

In repeating Hertz's experiments in the State Physical Laboratory at Hamburg, an observation was made which shows how in a simple manner we can overcome the difficulty experienced by many observers of keeping the primary spark effective for a long time together. In the same manner in which Rijke used the action of a current of air on the make-and-break spark of an induction-coil in order to produce a stronger action in the secondary coil, so may the spark of the coil itself, and therefore also its inductive action on any other conductor, be similarly influenced.

In the experiments a large Ruhmkorff's coil was used which had a very rapid contact-maker, and which gave sparks up to 14 centimetres. If the ends of the secondary coil are loaded with conductors, and the discharging knobs are brought within a distance of a few centimetres, the discharge takes place mostly in the form of a continuous rose-coloured strip of light, and is useless for Hertz's experiments. But when this band is blown away so that flames a centimetre in length project on the side, sharp brightly luminous sparks occur between the knobs. The current of air produced by a Müinke's water-pump was now blown continuously between the knobs, and thus a series of sharp cracking sparks passed quite continuously, and could without difficulty be continuously maintained for hours. A series of Hertz's experiments could now be repeated, and even when the current of air was replaced by one of steam the action was the same. The whole process suggests the idea that, in the ordinary discharge with a luminous band of light, detached metallic particles effect a permanent conduction, and that the essential discharge-spark is only produced as these particles are blown away. The influence of the ultra-violet illumination, too, which has been designated by various observers as highly disturbing, would, after the researches of Lenard and Wolf on the pulverisation of bodies by illumination, in this find an explanation.

* Abstract from the *Phil. Mag.*

THE COUPLING AND CONTROL OF DYNAMOS IN CENTRAL STATIONS.—II.*

(Continued from page 433.)

The main electrical governor in the last arrangement discussed can be made very accurate by means of relays balanced against a large Clark or other standard cell, and can also be made to respond very slowly, so as to avoid any chance of making the whole station "hunt." The slowness of response permissible depends on the quickness of variation of boiler pressure, and of variation of station load. Even with tubular boilers, such as Fashion, who is as autocratic in engineering as in dress, dictates for modern stations, the variation of steam pressure is not rapid, and the load on a central station also varies very slowly. High-speed engines with very little inertia are also in vogue just now, so it is easy to make a general station governor free from any danger of hunting. Many people would regard a Clark cell as unable to control a relay of sufficient power to be safe; but these cells are made small for balancing by Poggendorff's method with a sensitive galvanometer. A large Clark cell will give a fair current without damage. Almost any cell is more accurate than a voltmeter or solenoid arrangement. A secondary battery, for instance, balanced against the station pressure will give a very large power with a small variation of pressure.

As the governor may sometimes go wrong, and raise the E.M.F. throughout the station, thus breaking some thousands of lamps, it would be risky to give it complete control of a station, and to rely upon it absolutely. Controlling by hand is expensive, and is apt to be intermittent or occasional. It would therefore be infinitely better to combine the advantages of both systems by allowing the governor complete control within a margin of, say, 1 per cent., and relying on a thinking being for large adjustments. When the governor reaches the end of its tether, an attendant turns the whole station a half per cent. up or down, as the case may be. This must be done very slowly, so that the governor can have time to counteract it, thus keeping the pressure really constant. The governor is thus left at the middle of its range again. The control of an incandescent lamp station within a tenth per cent. or so is of enormous importance in connection with efficiency and lamp renewals.

Instead of electrically governing the engines the ordinary speed governors may be used, and the dynamos may be controlled by varying their excitation. The engines do not then really need to run at constant speed; all that is necessary is that for every speed there shall be a determinate steam supply, or, if the boiler pressure varies, that the speed will be constant within the limits of safety of the engine. Regulation by excitation then really becomes a roundabout method of controlling the steam supply, and nothing more. For if a machine is giving 100 volts and 1,000 amperes, the station pressure being 100 volts, and it is required that that machine shall only give 500 amperes and 100 volts, the field is weakened. If the engine had the same cut-off, so that its torque was constant, the speed would increase till the torque was as before. But as the field is weaker, this torque can only be obtained by delivering a current greater than 1,000 amperes. An engine giving constant torque driving a dynamo on constant pressure is thus in unstable equilibrium. Suppose, however, that the cut-off or throttle valve is controlled by a speed governor, on weakening the field the engine increases its speed till the governor cuts the steam down, and by weakening the field enough, the engine runs up till the steam supplied only gives a torque which, with that field, corresponds to 500 amperes. The regulation of the field is thus merely a method of turning on or off the steam, and nothing more. Of course, these remarks only apply completely to central stations under the conditions discussed. The regulation of the field of a dynamo driven from a shaft, which also drives, say, a machine shop, is not the

* Abstract of an article by Mr. James Swinburne in *Industries*, Aug. 22nd.

Digitized by Google

same, as the speed of the shaft, and therefore the governor and steam supply, do not wholly or even mainly depend on the torque in the dynamo.

In a station with each engine governed for speed it is perhaps best to arrange the governor so as to admit a fair variation of speed between no load and full load, as such governors are more easy to make, and in this case will do as well or perhaps better than if they were nearly isochronous.

As the load on a station increases the engines will need more steam, and to get this they must run slower. The fields must therefore be strengthened. In the case of shunt machines, which have a falling characteristic, as must especially be the case in large single-magnet dynamos, the variation of excitation necessary is considerable. To vary the station pressure all the shunts must be altered together; to vary the proportion of the load taken by each steam dynamo each field must be altered independently. At the St. James's and Pall Mall station in Mason's-yard, Mr. Dobson has arranged the shunts so that each is controlled independently by a lever, but all these levers can be thrown into gear with a master lever whatever their relative positions, and can then be controlled together. The master lever controls the pressure of the whole station, and the individual levers the proportion of load taken by each steam dynamo. If an electric pressure governor were used it would control the master lever. When shunt machines are used the margin for control must be great.

Compound machines may be coupled to run in parallel by Mordey's method of connecting all the brushes as well as the terminals. These connections are a little expensive, but, as will be explained, they save cost in other directions. The control is just the same as in the case of shunt machines, but there is the great difference that with uniform, or nearly uniform, boiler pressure the whole station compounds, so that there are no fluctuations of pressure caused by variations of load, or by putting in machines or cutting them out. In large machines, with great back induction, this means a great saving of resistance and regulating appliances. As a rule, station dynamos are only at light loads at the instant of coupling in, the working range being from half to full lead. If they are to be coupled in at full speed, the resistances for controlling a shunt machine must be enough to cause the whole variation of field. Generally a shunt machine is put into circuit at a lower speed with full field; but in any case it is advisable to have resistance enough to go through the whole range of the dynamo. This means a very large resistance board, and a very large drain of electrical power going to waste. Ten dynamos of 100,000 watts each may thus waste two or three horse-power among them on adjustable resistances. With compound machines nearly the whole of this waste can be saved. There seems, therefore, to be a heavy balance in favour of compound machines for station work.

Parallel coupled stations without batteries give most trouble when feeders are used. Feeders may be worked in several ways. The station pressure may be kept uniformly high—say, 2 per cent.—and the feeders may be thrown in as the load increases in such a way that there is always 2 per cent. drop in them. It may be preferable to make the whole station "compound up" a little—that is to say, give a higher pressure when the load is heavy. When feeders are not used this improves a direct supply. For instance, when the mains are arranged concentrically round the station with radial feeders, as at the Pall Mall station already mentioned, if the lamps are all 100 volts, the station may give 100 volts at light loads, so that all the lamps then have 100, the drop being negligable; at full load the station runs up to 101 volts, and the near lamps get 101, the medium 100, and the distant 99 volts, giving a maximum variation of only 1 per cent. This principle is equally applicable in the case of feeders, and lessens the cost and complication of the systems. The case of concentric service mains supplied by radial feeders is a particular case of districts fed by connecting feeders with no network of mains connecting the districts. In the case of a larger area, additional feeders can be run direct to the outlying districts. If the districts are all provided with lamps for the same pressure, and if the station is run in parallel, there must always be considerable waste of power in the feeders, unless the compounding-up half-way method is adopted; for the distant lamps must have full pressure, so the whole station must be run with the additional pressure lost in the feeders. In some cases the feeders are not thrown in and out, but have resistances inserted in them. The Edison station at Boston, for instance, is run this way. A certain percentage of the power of the station is then always allowed to run to waste either in resistances or in feeders. A great deal of this loss can be saved, however. Instead of arranging the feeders and resistances so as to have a constant drop in them the whole of the day, they may be regulated so that at any given time the drop in all the feeders is the same, though at different times the drop differs. For instance, in the day the station may be run at 100 volts with all the resistances out of all the feeders, so that there is no waste. In the early evening a shop district may be at full load, having a drop of two volts, while a residential district has a drop of one. The station is then run at 102 volts, and one volt is lost in resistance in the residential feeders. When the shop and residential district feeders each lose 1 volt, the station runs at 101 volts, with no resistance in either, and so on. The principle of "compounding-up" may also be applied here to some extent. The saving is very large compared with a constant drain, which is probably under-estimated at 2 per cent.

The feeder difficulty may be more economically treated by dividing the station into two parts. One is run at from 100 to 101 volts, and the other at from 100 to 102, according to the time of day. The distant feeders are connected to the latter part of the station, and the nearer districts are worked from the former. With a three-wire system this means no less than four divisions of the central station plant; but the connections and switchboards are but little more complicated than if the machines all run in parallel on direct supply. Of course, battery systems admit of feeder regulation in the greatest perfection; but the advocates of batteries are a little apt to overlook the extra cost of the switches and connection gear, and the troubles involved in uneven discharge of some of the cells.

(To be concluded.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 15, 1890.

Meeting of the National Electric Light Association.—The principal event in electrical circles just now is the coming meeting of the National Electric Light Association at Cape May. It promises to be very largely attended, and a number of out-of-town electricians are now in the city, on their way to the meeting, which will open on Tuesday morning next, and continue during the three following days. A large number of interesting Papers are promised, and some important Committee reports will be presented. The work of the Association itself is gradually growing in importance from year to year, and much good can be accomplished through their aid, because the National Electric Light Association represents more completely than any other organisation the electrical interests of this country.

Meeting of the American Association for the Advancement of Science.—During next week, too, the American Association for the Advancement of Science holds its annual meeting in Indianopolis. The report of the Papers to be read has not yet been made public, but it may be safely assumed that some at least of them will be of special interest to electricians. In years past some very important work has been done by the American Association, even in practical electricity, and there is a strong probability that the present meeting will be no exception to the rule. These meetings are usually well attended, although but small compared with the immense gatherings at the meetings of the British Association, owing to the scattered nature of its membership.

Storage Battery Cars.—Some progress seems to be made in equipping the Fourth Avenue street-railway with storage battery cars. For a long time only a single car was in operation, but the United Electric Traction Company, the successors of the Julien Company, are now putting on cars as rapidly as the batteries can be turned out of the factory and placed in position, and a tolerably complete service is promised ere long. Speaking of storage battery cars, a new one has just been tried on the Seventh Avenue surface line with a fair degree of success. It is the MacDougal storage battery car, and while not radically different from the others now in use, it presents some admirable mechanical features.

The Van Depoele Closed Conduit System of Electric Traction.—Mr. C. J. Van Depoele, of the Thomson-Houston Company, has recently patented a closed conduit specially for electric traction service. It consists of a small subway laid in the usual position and furnished with a slot in which the contact plough runs as usual. A peculiarity of the system is that the slot is completely closed except where it is held open by the plough under the car by a pair of flexible lips of insulating material—rubber or its equivalent—so that dirt and water are

Digitized by Google

in great measure excluded from the conductors. Of course, very little can be said regarding the practical effectiveness of this plan until it has been given trial on a large scale; but if the slot closing material can be made sufficiently durable, many of the difficulties of insulation would appear to be overcome.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *August* 21, 1890.

The manufacture in Sweden of various electrical appliances is constantly increasing, and several of the articles have attracted considerable attention outside this country, as, for instance, both dynamos and telephones, electric wires, &c. Sweden is also now doing a fair export trade in incandescent lamps, especially to Russia. The principal makers, R. W. Strehlenert and Co., of Stockholm, have just executed an order from Norway for 10,000 incandescent lamps, and are altogether doing a very good trade. The Elektriska Aktiebolaget in Stockholm has during last year sold 38 dynamos of 501 electrical horse-power, and installed 4,234 incandescent and 16 arc lamps. Among last year's more important installations were the central electric stations at Arboga and Östersund, comprising about 120 subscribers and 200 street lamps. During this season 156 dynamos of 1,880 electrical horse-power have been made at the Company's works, and 17,400 incandescent and 35 arc lamps have been installed. For the past two years the Company has paid a dividend of 5 per cent.

During the first half of the present year the number of telegrams in Sweden amounted to 440,309 inland and 368,832 foreign, the receipts amounting to 308,633kr. and 336,927kr. respectively. There was an increase in the number of telegrams, as compared with same period last year, of 19,732 messages, or 2·5 per cent., of which 11,784 telegrams were inland ones; the receipts have, however, decreased by 3,359kr.

There have been a great many heavy thunderstorms lately, both in Denmark and Sweden, and much damage has been done to property, and several fatalities have occurred. The lightning has in some places acted in a most capricious manner. At one place, at Suöresjö, in Sweden, it did a great deal of damage in a house—split up a lot of woodwork, tore the wall paper from off the walls, &c. The greatest damage was done in two rooms, where, altogether, ten people were asleep, but none of them sustained any injury. At Nestoed, Denmark, some men, who had been repairing a lightning conductor, had just left it when the lightning struck it.

CORRESPONDENCE.

ELECTRICAL NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The importance of the above subject must be my excuse for troubling you with a few remarks on Dr. Fleming's letter, published in your last issue, especially as the writer, in his final sentence, invites discussion.

On this side of the Atlantic we will, I am sure, be only too ready to entertain the proposal of our American colleagues to embody the names of Henry and Franklin in the system of practical electrical units. But in addition to the principle adopted by the British Association Committee in 1862 of forming the names of practical units out of the surnames of distinguished investigators, it seems to me that a subsidiary condition should not be lost sight of. It is this: that the name or the contraction of the name by which any unit is to be known should not be identical with or even closely resemble any word in common use to which other associations are attached. Up to the present, the names that have survived have fairly well fulfilled this subsidiary condition, though the word "watt" sails somewhat close to the wind in this respect. But Dr. Fleming's suggestion to adopt the word *hen* as the practical unit of self-induction opens up a vista too terrible to contemplate. One cannot, indeed, resist a suspicion that the learned doctor, by his suggestion and by the remorseless way in which he follows it out to its logical results in speaking of *true hens*, *legal hens*, *henmeters*, &c., intends to demonstrate once for all that the word *Henry* is quite intractable for the purpose in view. Even if the full name were taken it would be apt to degenerate, at least with Cockneys, into a too well-known abbreviation.

There is another consideration which should also be borne in mind, and that is, that there are living "distinguished investigators" who have certainly earned the right to have their surnames canonised in this way. It would be well, therefore, not to be in too great a hurry to cover all the ground. Moreover, we have no unit whose name is derived from the honoured name *Maxwell*, a word which looks at first sight not very tractable, though perhaps the ingenuity of word-coiners may yet make something of it.

Turning now to Dr. Fleming's other proposals, I agree with him that the term "magnetic resistance" should be dismissed, but I would replace it by Mr. Oliver Heaviside's term "magnetic reluctance," which seems to express neatly the ideas that underlie the phenomena as we at present view them. Just as the reciprocal of resistance is conductivity, so the reciprocal of reluctance could be known as *receptivity*, or, still better, *receptance*, the old term "permeability" being retained for the "specific receptance" in C.G.S. units. The word "permeability," except for the fact that it is one syllable longer, seems preferable to "pliability," and is already well known.

Dr. Fleming's definition of the practical unit of the total flux of magnetic induction and the name that he proposes for it are urgently needed for practical work, and I hope that they will be adopted, though personally I should prefer the full word *gilbert* instead of the contraction *gilb*, which could, however, be used by those who are laconically inclined. Again, I should prefer the full word *franklin* to the contraction *frank*, especially as the latter trenches upon familiar associations. But I hope that Dr. Fleming's definition of the *frank*, by whatever name it may be known, will be simplified. Supposing the ampere and the ohm already fixed we should scarcely proceed to define the volt "by the condition that a uniform slope of electric potential along an electric circuit of one volt per centimetre of length produces an electric current of one ampere per (square) centimetre of cross-section in that circuit, when that circuit consists of material of unit specific resistance." This definition, however, would be correct. In the definition proposed for the gilb(ert), it is recognised that the total magnetic induction is more important than the "density of or intensity of induction." Why not consistently follow out this idea by defining the frank(lin) as that magneto-motive force which will produce one gilb(ert) in a circuit of unit magnetic reluctance? If, in addition, we take as the practical unit of magnetic reluctance, one-millionth part of the C.G.S. unit, then the frank(lin) would be 80 ampere-turns, to the same degree of approximation as is used by Dr. Fleming for his "microfrank." The specific reluctance of air and non-magnetic materials would be 1,000,000 of these practical units, a fact which would serve to impress on the minds of practical men the great influence which an air-gap has on the reluctance of a circuit. A convenient name would doubtless soon be found for this unit of reluctance.

The chief difficulty, however, is with regard to the tables of "specific reluctance," from which the total reluctance has to be calculated. But Dr. Fleming's suggestion only appears to remove the difficulty for those circuits which are of uniform cross-section, and of the same kind of material throughout. These are not the circuits with which we have frequently to work in practice; instead we have circuits of wrought and cast iron of different cross-sections with air-gaps interposed. One obvious way out of the difficulty is the following:—The total number of gilb(ert)s required is generally known, at least approximately; the cross-section of iron where the magnetic flux is greatest can also be approximately assigned. Tables (or preferably curves) could be constructed giving the specific reluctance of the particular kind of iron for various magnitudes of the magnetic flux, in gilb(ert)s per some unit of area which would be most convenient for practical men, and from these a calculation could be made of the reluctance of the whole circuit, with recognised allowances for leakage in standard cases. The requisite magneto-motive force in frank(lin)s could then be calculated by the Ohm Law rule.—Yours, &c.,

R. MULLINEUX WALMSLEY.

Heriot-Watt College, August 26, 1890

"CATAPHORIC MEDICATION."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your Note on "Cataphoric Medication," which term I believe I am responsible for, you are good enough to remind your readers that the process is regularly practised at the Institute of Medical Electricity. So true is this, that I am hoping shortly to bring before one of the learned societies a considerable series of actual cases in which cataphoresis has been practically applied with satisfactory results. At a lecture on November 5, 1889, to a class of medical men and nurses, at the Institute, I showed cases, including rheumatoid arthritis, under this treatment. At the meeting of the Brussels Medical Graduates' Association, in December, 1889, I again spoke on the subject; and in a letter to the *Medical Press* on December 11, 1889, I described in some detail the process employed in my cases. I am very glad to be supported by so well-known an electrician as Mr. Edison in the investigation of this subject; but I think he is a little late in the field, though he has been somewhat premature in the publication of a solitary case which was only "temporarily ameliorated."—Yours, &c., ARTHUR HARRIES, M.D.

14, Suffolk-street, Pall Mall, August 23, 1890.

A LONG-LIVED INCANDESCENT LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was surprised to read on page 397 (August 15) that 3,500 hours is considered to be a "phenomenal" life for a modern incandescent lamp. I have before me a 100 volt 16 candle-power Edison-Swan lamp, which has a record of 6,011 hours. This is one of 430 installed in the Victoria Hotel, Manchester, in March, 1888. One of these is still doing duty, never having been disturbed except to clean the shade occasionally, and then not removed from the socket. This lamp has a record of 10,418 hours up to noon to-day. It has been repeatedly run at 110 to 115 volts, though only for one to six or seven minutes consecutively. On one occasion during the early days of its existence it was, together with about 200 other lamps, subjected to an E.M.F. of 120 volts for some fifteen to twenty minutes. At this time twelve lamps gave out, but not so the above-mentioned "phenomenal" lamp.

O! si sic omnia! Should the filament ever give out I will advise you of the fact.

Mr. R. Boyd, the engineer in charge, can vouch for the accuracy of the above statements. I should add that the average life of the lamps has been over 2,000 hours.

One of my clients, who habitually runs his lamps (100 volts) at 130 to 140 volts, finds that the average life is rather over 200 hours.—I am, yours, &c., J. LAVENDER, JUNR.

Manchester, Aug. 26, 1890.

[It will be interesting to see whether Mr. Lavender's undoubtedly phenomenal lamp will be longer lived than the one referred to in the *Electrician* of November 22, 1889, by Mr. O. V. Thomas. This lamp did duty for 10,608 hours, and also suffered somewhat from overrunning.—ED. *E.*]

"GLOBULAR LIGHTNING."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The full particulars given by Mr. Adamson in your number of the 22nd inst. of this form of electricity are very important, he and the boy having both seen the ball moving, The spheroidal state of electricity is one among other proofs that this element possesses a certain amount of attraction of cohesion for its own particles. If it did not possess attraction of cohesion it would never exist as a sphere, and is a proof that it does not possess repulsion for its own particles; which latter doctrine is a part of Faraday's delusion, that electricity is two forces, each individually repellent to itself.—Yours truly,

JAMES JOHNSTONE.

Laboratory, Dalhousie-terrace, Edinburgh,
August 25, 1890.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The British Foreign Office announce that the Spanish Minister of the Interior, by a notice dated the 18th inst., invites tenders for the construction of a line of telegraph cables between Spain and the Spanish possessions on the north coast of Africa, and to Tangier. Seven sections will be required, of a total length of 332 miles. The maximum payment to the contractor is not to exceed £160 per mile. Tenders, in sealed covers, are to be addressed to the Director of Posts and Telegraphs, Telegraph Department, No. 18, Calle d'Claudio Collo, Madrid, on or before September 17th. The conditions of the contract (in Spanish) can be seen at the Commercial Department of the Foreign Office, Whitehall, between 11 and 5.

MESSRS. DRAKE AND GORHAM.—We understand that Messrs. Drake and Gorham have found it necessary to double the size of their existing offices to find accommodation for the additional *employés* which they have been obliged to take on, owing to the rapid increase of their business.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.

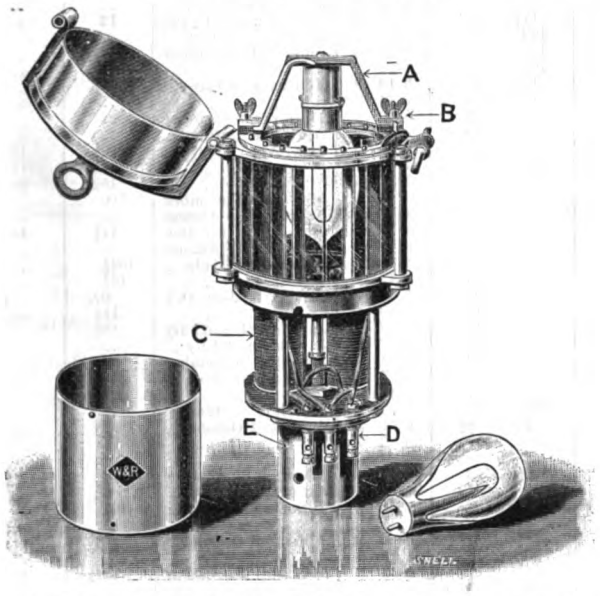
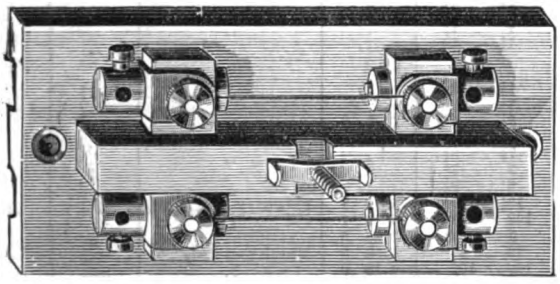
SCOTT'S FLASH-SIGNALLING LANTERN.—This lantern, the invention of Commander Percy Scott, R.N., is manufactured by Woodhouse and Rawson United (Limited), and was fully described in our issue of June 20th, p. 171. The accompanying block shows Commander Scott's lantern with its shutters open, when no current is flowing, and with its cover and tube removed to show the



inner details. A is the holder, which, by unscrewing the fly nuts B, enables the lamp to be at once removed for the substitution of a new one; at C are two magnet coils, actuating the armature; and at D are three terminals respectively joined to the magnet coils, the lamp, and one dynamo terminal. The framework supporting the shutters is removable. E is a stout tube enabling the lantern to be fixed on the top of a mast, to which it is pinned through the hole seen in the side. It can also be suspended from the ring attached to the cover.

BINSWANGER'S IMPROVED "H.I." CUT-OUTS.—An excellent form of cut-out has been introduced by the General Electric Company,



the construction being very well adapted for maintaining a high insulation from earth. The body and the cover are of china, and the metal parts are carried on ribs moulded on the body, thus avoiding any appearance of screws at the back. The filling up of the back of fittings with insulating material to prevent leakage from screw heads is not reliable, and the arrangement of the "H.I." cut-out not only dispenses with this, but in single pole cut-outs provides a wall of china separating the conductors from the fuse. The large sizes are provided with tinned thimbles for sweating on to the ends of the cables. The covers are readily removable, and the fuses are easily got at. The accompanying illustration shows a double pole cut out, an article of which we do not approve, but which is sometimes demanded.

THE BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.—This Company have entered into a contract with the London Road Car Company for the supply of 60 omnibuses for horse traction. These omnibuses will be constructed at the Brush Company's Falcon Works, Loughborough, where large extensions have been made to enable the Company to cope with the increasing demand for their steam engines, tram cars, and omnibuses for electric or other traction, rolling stock, and electrical machinery and apparatus of every description.

NEW COMPANIES REGISTERED.

CERES IRONWORKS (LIMITED).—Registered with a capital of £15,000 in £10 shares. Object: To carry on the business of general and mechanical engineers, metal founders, and implement makers, &c., at the Ceres Ironworks, Kingston-on-Thames.

UNITED FLEXIBLE METALLIC TUBING COMPANY (LIMITED).—Registered with a capital of £75,000 in £10 shares. Objects: To acquire and amalgamate the undertakings of the Flexible Metallic Tubing Company (Limited), incorporated in 1886, and of the Belgian and Colonial Flexible Metallic Tubing Company (Limited), and to carry on the business of manufacturers of and dealers in flexible and other metallic tubes, &c.

VAUGHAN-SHERRIN ELECTRICAL ENGINEERING COMPANY (LIMITED).—Registered by Lowles and Co., 26, Martin's-lane, E.C., with a capital of £25,000, in 4,975 ordinary shares of £5 each and 25 founders' shares of £5 each. Object: To carry into effect an agreement, made August 11th, between John Vaughan Sherrin of the one part and Richard Frederick Dempster, on behalf of the Company, of the other part, and to manufacture electric motors, generators, tricycles, bath-chairs, boats, and machines, or any carriage, vessel, or machine, either wholly or partly propelled or worked by electricity, upon any system whatever, and for carrying on the business of electrical and mechanical engineers, and all manufactures connected therewith or relating thereto. Mr. John Vaughan-Sherrin is appointed Managing Director at a salary of £300 per annum.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 22nd amounted to £5,121.

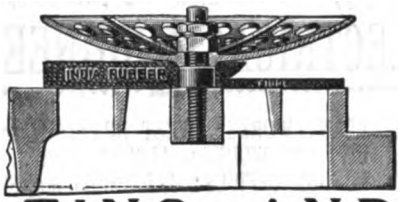
ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—We are informed that better prices for their manufactured goods are being obtained by this Company than was expected, and that a saving has been effected upon cost of manufacture. The £2 shares of this Company have recently touched £8, and closed yesterday at £7. The formation of the Elmore Wire Company no doubt contributed largely towards providing the funds for the big dividend the parent Company has been able to pay. We must wait till we are supplied with statistics as to cost and have experience of the value of the products of the Company before deciding whether the quotations given above represent the real value of the shares. The tubes and wire shown by the new Company at their offices in Queen Victoria-street certainly go far to bear out the sanguine views of the Directors, and to prove the commercial value of the process. We are informed that the Company has large orders on hand.

STOCK EXCHANGE.—The Committee have ordered the under-mentioned security to be quoted in the official list:—Electric Construction Corporation (Limited), shares, Nos. 101 to 45,100.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 22, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,994.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 20th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 642.—Vol. XXV. FRIDAY, SEPTEMBER 5, 1890. Price Fourpence.

NOTES.

The Presidential Address delivered yesterday by Sir Frederick Abel before the British Association at Leeds was of a length commensurate with the importance of the occasion, and contained a large amount of matter of considerable interest to electricians. No one is better qualified than Sir Frederick Abel to speak on what may be termed "military chemistry;" and although he had, of course, much to tell us with regard to smokeless powders and modern explosives generally, he by no means confined himself to that particular branch of applied science with which his name is so intimately connected.

Electricity and the progress it has made since the Leeds meeting of 1858 formed the theme of an interesting historical review. What has been accomplished in this direction during the last thirty-two years is well known to us all; but we think that it will come as a surprise to many to hear that thirty-four years ago Joule had closely studied the question of welding metals by electricity, and seems, indeed, only to have been prevented by the lack of suitable electrical generators from making that practical application of his investigations which has been made in our day by Elihu Thomson. A careful search into the scientific records of the past would no doubt reveal many similar correctives to our exalted notions as to the wonderful nature of the advances of the last decade or so.

One fact greatly emphasized and amply illustrated by Sir Frederick Abel in the course of his address was the action and reaction between theory and practice which is ever going on; and his remarks on "the invaluable aid afforded to purely scientific research by the practical results of the development of electrical science, and of the constant co-operation between the science student and the practical worker," are well worthy of perusal by those super-energetic spirits who are ever seeking to start barren discussions as to the relative utility of theoretical and practical men, and to apportion in a hard and fast manner their respective shares in the advancement of science

The concluding portion of the President's address dealt with Technical Education and Science Museums, and contained a handsome eulogy of the public spirit shown by Guilds of the City of London in so munificently endowing this department of education. "To have been first in the field in practically developing a far-reaching scheme for the advancement of technical education in this country must," said Sir Frederick, "continue to be a source of pride to the City of London and its ancient Guilds in time to come, when the operation of efficient legislation, supported and extended by patriotic munificence and by the hearty co operation of associations of earnest and competent workers in the cause, shall have placed the machinery and resources for the technical instruction of the people upon a footing commensurate with our position among nations."

The employment of electrical methods in chemical research is becoming more and more common. The study of the electric resistance of solutions has already been of service in investigating their nature; and, in the hands of Prof. Mendeléeff and his followers, has resulted in the discovery of new compounds. The close connection between the electromotive force of a cell and the energy corresponding to the thermal actions within it was pointed out many years ago by Sir W. Thomson, and is now chiefly used to determine the chemical actions within the cell. Electrical methods are, however, not so much used in chemical research as their importance warrants; and the valuable Paper of Dr. Gore, an abstract of which we reproduce in another column, will be serviceable in this connection by bringing the subject prominently forward.

Electrical methods of test are far more sensitive than chemical ones, since with the former the tendency to chemical action is measured, while with the latter it is only after the action has gone on for some time that a sufficient product is formed to be recognisable by chemists. The electrical method is, in fact, so sensitive that great care and skill are needed to reproduce results; and the employment of pure materials is absolutely necessary, since the presence of slight traces of foreign substances, too minute to be detected chemically, is sufficient to alter the indications. The simultaneous study of the electrical properties of analogous chemical compounds, although of great importance, has not before been attempted; and the relations brought out by Dr. Gore between electromotive force and molecular weight are very interesting and suggestive. The seat of chemical energy in the voltaic cell is clearly indicated by the curves, showing the effect of varying the strength and temperature of the solution at one electrode; while the employment of the method to detect the influence of light, heat, &c., on different solutions may lead to a more accurate knowledge of the conditions necessary for the formation of a good standard cell.

In another column will be found an abstract of a recent article in the *Electrical World* of New York, which would appear to afford a striking argument in favour of the use of high-speed engines coupled direct to the dynamos for electric traction work. About this time last year Dr. Louis Bell carried out some tests on the Sprague line at Lafayette (Ind.), where power was supplied by a slow-speed Hamilton-Corliss engine, and he worked out the average commercial efficiency of the system at the low figure of 25 per cent. In the present article the average efficiency of a Thomson-Houston line at Syracuse, New York, where power is obtained from Armington and Sims engines, came out at 37 per cent., the station efficiency being 62·8 per cent., as against 40·7 per cent. at Lafayette. As the length of the lines is not very different and the number of cars running at the time of the tests was the same, the results would appear fairly comparable. It should be mentioned, however, that the Lafayette line contains far more curves and gradients. An average efficiency of 37 per cent. is certainly a great advance upon one of 25 per cent., but electrical engineers are not likely to rest content until a much higher figure is attained. Large motors geared direct to the axle will doubtless come into general use in due time, and may be expected to give better results than any we have to show at present. One cause of the low efficiency of electric street railways has, however, we think been somewhat overlooked. We refer to the smallness of the number of cars usually run. When there are lines at work with 50 to 100 cars in operation, we may reasonably look for a higher efficiency than is obtainable on small lines, where the demand for power is continually varying from zero to maximum, in a manner which is scarcely conducive to high efficiency.

The efficiency of electrical railways also forms the subject of a leading article in the *Engineer* of last week; and, taking the results of some tests on the Manhattan Elevated Railway, a very poor case is made out, and electrical traction is found to compare very unfavourably with propulsion by steam. We have some diffidence in criticising the opinions expressed by our contemporary, since it is a recognised authority on railway matters, and we are fully aware that the electrical engineer who proposes to go into the subject of traction has much to learn from railway practice. We should, however, never think of taking an American test as a source of information as to what is the utmost possible in the matter of efficiency. We all know that there are hundreds of miles of electric lines in daily work in the United States; but, from what we hear, they are designed and carried out in much the same style as the electric lighting. Mr. Addenbrooke's Paper is fresh in the minds of most of our readers; and they will doubtless remember the candid way in which excuse was there made for rough-and-ready work. Such work, most visitors to the States admit, would not be tolerated here for a day; but since it satisfies our friends on the other side, it is no part of our business to offer criticisms. On these grounds, even if "the efficiency of the entire plant was 15·1 and the average loss was 84·9 per cent.," we should not be prepared to pronounce that the case was an utterly bad one; but if Messrs. Mather and Platt do not do twice as well as this in the Subway, we shall be surprised.

Without going into the definition of the "success" of any engineering enterprise, we think that the term is yet more ambiguous than our contemporary seems to suggest. In many respects "steam locomotives comply with all the demands which are made on them, so far as doing their duty is concerned;" but the day has come when we want a locomotive which shall be lighter than the whole of the rest of the train which it draws, and a steam generator which can be designed without regard to bulk or weight. In tramway work we admit that the main question is the cost per car-mile compared with horse-traction; but the reduction of the weight of the rolling stock by 60 per cent. or more, with the consequent lighting of the permanent way, and facilities for such lines as that which is being built at Liverpool, and the absence of vitiated and sulphurous air, are questions which will hold their own in spite of even a higher cost for working. Admitting that "there is a certain speed for a motor at which its efficiency is a maximum, and at all other speeds its efficiency decreases," the increased torque at starting, with a heavy current, is clearly comparable to the large steam consumption when the links are notched down, as is pointed out in the report on the tests, and is not altogether a weak point in electrical traction.

A method of electrical welding has been brought out by a Mr. Coffin, of Detroit, which, although put forward as something new, is practically only a development of the process of Dr. Bernados, which was described in *The Electrician* of November 25th, 1887, Vol. XX., p. 58. The method has none of the admirable automatic properties of the Thomson electric welding system, and merely employs the radiant heat of the arc for heating the metal; the advantage being, as was stated in our description of the Bernados process, that the heat is taken to the place required, instead of having to bring the metal to the forge. Mr. Coffin in some cases uses two arcs between two pairs of carbons arranged one on each side of the pieces to be welded. The only novelty in the account of his methods of welding is the localising of the current by means of a powerful magnetic field concentrated in the required direction.

A second Paper has been published by Messrs. Herzog and Stark, of Buda-Pesth, on the theoretical predetermination of current distribution in a network of electrical conductors, and the authors have favoured us with a translation of it. In the midst of diagrams of imaginary conductors and series equations and determinants, we find that among other results they arrive at the conclusion that "several concentrated loads or a distributed one between any two neighbouring nodal points may be reduced to one concentrated load equal to the algebraical sum of these loads, and tapped from the common centre of gravity." Whether these calculations are of interest to pure mathematicians, we cannot say; but we had some little doubt as to their practical value to the engineer who has to design and arrange mains for the distribution of electrical energy in towns from central stations. To satisfy ourselves, however, on this point, we submitted the Paper to an engineer who is engaged in this very work for one of the principal supply companies in London, and we were not surprised to learn that such theoretical investigations are of no use in practice.

EVEN the work of Prof. FORBES, though it served a good purpose at the time, is of comparatively little service in the daily work of one who has to arrange such matters for actual execution. One result of Prof. FORBES' Paper at all events was to show that distribution over considerable areas by a simple low-tension service was hopeless, and his memorable copper conductor (28 metres wide and 1 centimetre thick), to carry 70,000 amperes, which was warranted not to warm the pavement more than 10° centigrade, probably contributed to the development of alternate current and other methods of distribution at high pressure.

THE calculations of the Hungarian authors are amplifications of those bewildering "relations" of KIRCHOFF which we happened to select as a subject for study when first beginning to unlearn the early electrical science acquired from the works of Prof. PEPPER and Dr. LARDNER.

THE West Coast of America Telegraph Company held a meeting, with closed doors, on Monday last. It was, however, an open secret that Sir JOHN PENDER was appealed to to do his best to help the Company in the way of negotiation, so as to avert the effects of the threatened competition. It is understood that Mr. MARSHALL, the Chairman of the Company, is to interview Sir JOHN PENDER to obtain his opinion, so as to bring about a better state of affairs. The shareholders were well pleased with the suggestion that Sir JOHN'S assistance and advice should be obtained.

THE present issue of *The Electrician* contains a steel-plate portrait of Dr. OLIVER LODGE. The portrait has been engraved from a fine photograph taken by Maull and Fox, of Piccadilly.

Electric Traction in Spain.—Electric tramways are to be opened between Bilbao and Santurce, and between Barcelona and Sarria.

Submarine Cable Extensions.—The telegraph steamer "Amber" has arrived at Zanzibar with the Zanzibar—Dar-es-Salaam—Bagamoyo cable on board.

Melbourne.—According to *The Times* correspondent the streets of Melbourne are partially lighted by electricity, owing to the failure of the gas supply consequent upon the gas-stokers' strike.

Edinburgh.—At the last meeting of the Town Council a report by the Lord Provost's Committee, "recommending notice of meeting to resolve to take action under the Electric Lighting Acts," was adopted.

Porsonal.—The future address of Mr. Arthur C. Cockburn (late manager of the Acme Electric Works) will be 22, Streatley-road, Brondesbury, where he will practise as a Consulting Electrical Engineer.

The "Electrical World."—The National Electric Light Association issue of the *Electrical World* of New York consisted of 98 pages, and is claimed as the largest number of an electrical journal that has ever been issued.

The Vienna-Brunne Telephone Line.—This line is to be opened during the present month. According to the *Elektrotechnische Zeitschrift*, an extension of the line from Brünn through Iglau to Prague is projected.

The Popp System in Hanover.—Dr. O. Gusinde, who was engaged to report on the adoption of the Popp compressed air system for the distribution of power in this town, has expressed his opinion in favour of the distribution being effected by electricity.

Weybridge.—The Chertsey Rural Sanitary Authority have given their consent to the granting of a Provisional Order by the Board of Trade, to authorise the supply of electricity in Weybridge by the Laing, Wharton and Down Construction Syndicate.

Strike at the Westinghouse Works at Pittsburgh.—The strike of the Westinghouse Electric Company's, Pittsburgh, employés, determined upon at a previous meeting, went into effect on August 11th. Both plants are shut down, and about 1,200 men are idle. The men demand shorter hours.

The Telephone on the Congo.—The steamship "Ville de Maranaho," which recently left Antwerp for the West of Africa, had on board all the necessary material for a telephone line which is to be run along the Congo railway. The wires are to be of phosphore bronze, and the Dejongh telephone will be employed.

The Telephonic Transmission of Music in Berlin.—An experiment was made on Tuesday last in transmitting operatic music by telephone from the Opera-house to the Urania Theatre of Science. It was a complete success. It is hoped in Berlin that it will be possible to make an arrangement with the telephone exchanges to furnish other places with music through the telephone.

Lewes.—An offer has been received from the Gülcher (new) Electric Light and Power Company to undertake the lighting of the streets of this town. It is proposed to use 240 16-candle power incandescent lamps, to be distributed over seven and a half miles of streets. The Company undertake to start the running within 16 weeks of the receipt of order. The present gas contract terminates at Christmas.

Railway Rates.—The Board of Trade have been unable to come to an agreement with any of the six Railway Companies on whose classification and schedule of maximum rates reports have been presented to Parliament; and they will therefore employ the time before next Session in considering any facts and figures which may be laid before them, before embodying in a Provisional Order the classification and schedule which they think ought to be adopted.

Glasgow.—It is expected that active steps will very shortly be taken for putting in operation the provisions of the Glasgow Electric Lighting Provisional Order. It has not yet been determined by the Glasgow Corporation whether the Provisional Order shall be administered by the Gas Committee, or by a Special Committee appointed for the purpose. It is urged by some that the administration of the terms of the Order would be safer in the hands of a Committee elected for the purpose than in those of the Gas Committee.

The Late M. Lucien Gaulard.—A bas-relief in honour of the late M. Lucien Gaulard was recently inaugurated at Larrzo, a small town 30 miles away from Turin. This "acte de justice réparatrice," as it is termed by *La Lumière Electrique*, is due to the initiative of Prof. Alexandre Volta. The following inscription is engraved in gold letters beneath the bas relief: "Here in the year 1884 Lucien Gaulard, of Paris, overcame, for the first time, by means of alternating currents, the difficulties of transmitting electric energy to long distances."

The Copper Market.—According to Messrs. H. R. Merton, there has been an increase in the deliveries of 537 tons for the month of August, compared with July, while the total supplies in England and France are now no more than 9,393 tons, against 11,470 tons in the previous month. Stocks have therefore declined over 2,000 tons, and now stand at the comparatively low figure of 69,959, as compared with 106,000 tons at this time a year ago. The price of copper has now risen to £60. 10s., or about the highest point touched since the collapse of the French syndicate last year.

The Currie Automatic Switch for Accumulators.—In this switch the scum which is produced on the surface of the electrolyte of an accumulator towards the termination of a charge is made use of. Two pieces of metal are arranged one over the other, just above the level of the liquid, in circuit with a battery, an alarm bell, and a switch actuated by an electromagnet. When the cells are well charged the accumulation of scum on the surface of the electrolyte completes the circuit

Digitized by Google

between the two strips of metal, which rings the bell and switches the cells out of the charging circuit.

The Effect of the Electric Light upon the Consumption of Gas.—At the recent meeting of the Congrès de la Société Technique du Gaz at Lyons, M. Le Roy produced some figures showing the effect of electric lighting upon the consumption of gas in France and abroad. The figures obtained, however, related only to 23 towns, 6 of which had no central lighting-station, 13 had central stations competing with the gasworks, and in 4 the Gas Companies also worked the electrical supply systems. The increase in the gas consumption during the past four years was 24·1 per cent. in the first instance, 13·85 per cent. in the second, and 16·5 per cent. in the third. From these figures it would seem that from the Gas Companies' point of view the next best thing to having no central lighting-stations is to run them themselves.

Birmingham.—The laying of the electric light mains is now being vigorously carried on by the Birmingham Electric Supply Company. The feeding mains are of bare copper strip, strained up and resting on glass insulators fixed in concrete culverts under the footways. The distributing mains are of insulated cables, laid in cast-iron troughs, and surrounded with bitumen. It is intended to charge 8d. per unit; the Company having power under their provisional order to charge 10d. per unit. Among the buildings which the Company have already arranged to supply are the Victoria Law Courts, the Grand Hotel, Colmore-row, and the branch Bank of England, Temple-row. In the Victoria Courts provision is being made for about 700 lights, and in the Grand Hotel for 200. In all these cases the internal work is being done by the Company.

City and Guilds of London Institute.—The programme of technological examinations of the Institute and of its associated Colleges covers a very wide range of subjects, the majority of them relating to different trades. Certificates are given both in ordinary grades, and with honours. Candidates for the former have to pass at least the elementary stage of the Science and Art Department's examination; and for the latter an examination in geometry, physics, and chemistry. In Electricity there are three sets of examinations, viz., Telegraphy, Electric Lighting and Transmission of Power, and Electrical Instrument Making, the examiners being Mr. Preece and Dr. J. A. Fleming. The examination papers, which are given in full, indicate that the teaching is thorough, though the training which can be given by the registered teachers in various parts of the country must be of a very different character to that of the Central and the Finsbury branches.

Telegraphy during the Commune.—One of the first things to be done after the recent disastrous fire at the New York offices of the Western Union Company was to re-establish the identity of each of the maze of wires running into the premises. Experienced electricians being on the spot, the task was not a very difficult one, and in a single day 300 circuits were restored. The ease with which this work was carried out at New York recalls to our mind, says *La Lumière Electrique*, a very instructive historic incident which occurred during the Commune. When the Republican Government quitted Paris, the operators at the central office in the Rue Grenelle managed to mix up all the wires before leaving. The Communists were so ignorant of everything connected with telegraphy, that it was beyond their powers to unravel the wires; and during the whole time that they were in possession of the building, namely, from the end of March to the end of May, they were only able to use the military lines. M. Fabre de Lagrange, who was forced to accept the appointment of chief electrician to the Commune, took good care to keep the wires in confusion; and, amongst other services to the State, he sent misleading telegrams, and thus saved many public and private buildings which the rebels wished to blow up by using an explosive mixture of air and coal-gas. These facts were clearly authenticated by the Court-martial which tried M. Lagrange, and he was honourably acquitted.
